

Chapter 8

Security

*Computer
Networking: A Top
Down Approach*
7th Edition, Global Edition
Jim Kurose, Keith Ross
Pearson
April 2016

Chapter 8: Network Security

Chapter goals:

- understand principles of network security:
 - cryptography and its *many* uses beyond “confidentiality”
 - authentication
 - message integrity
- security in practice:
 - firewalls and intrusion detection systems
 - security in application, transport, network, link layers

Chapter 8 roadmap

8.1 What is network security?

8.2 Principles of cryptography

8.3 Message integrity, authentication

8.4 Securing e-mail

8.5 Securing TCP connections: SSL

8.6 Network layer security: IPsec

8.7 Securing wireless LANs

8.8 Operational security: firewalls and IDS

What is network security?

confidentiality: only sender, intended receiver should “understand” message contents

- sender encrypts message
- receiver decrypts message

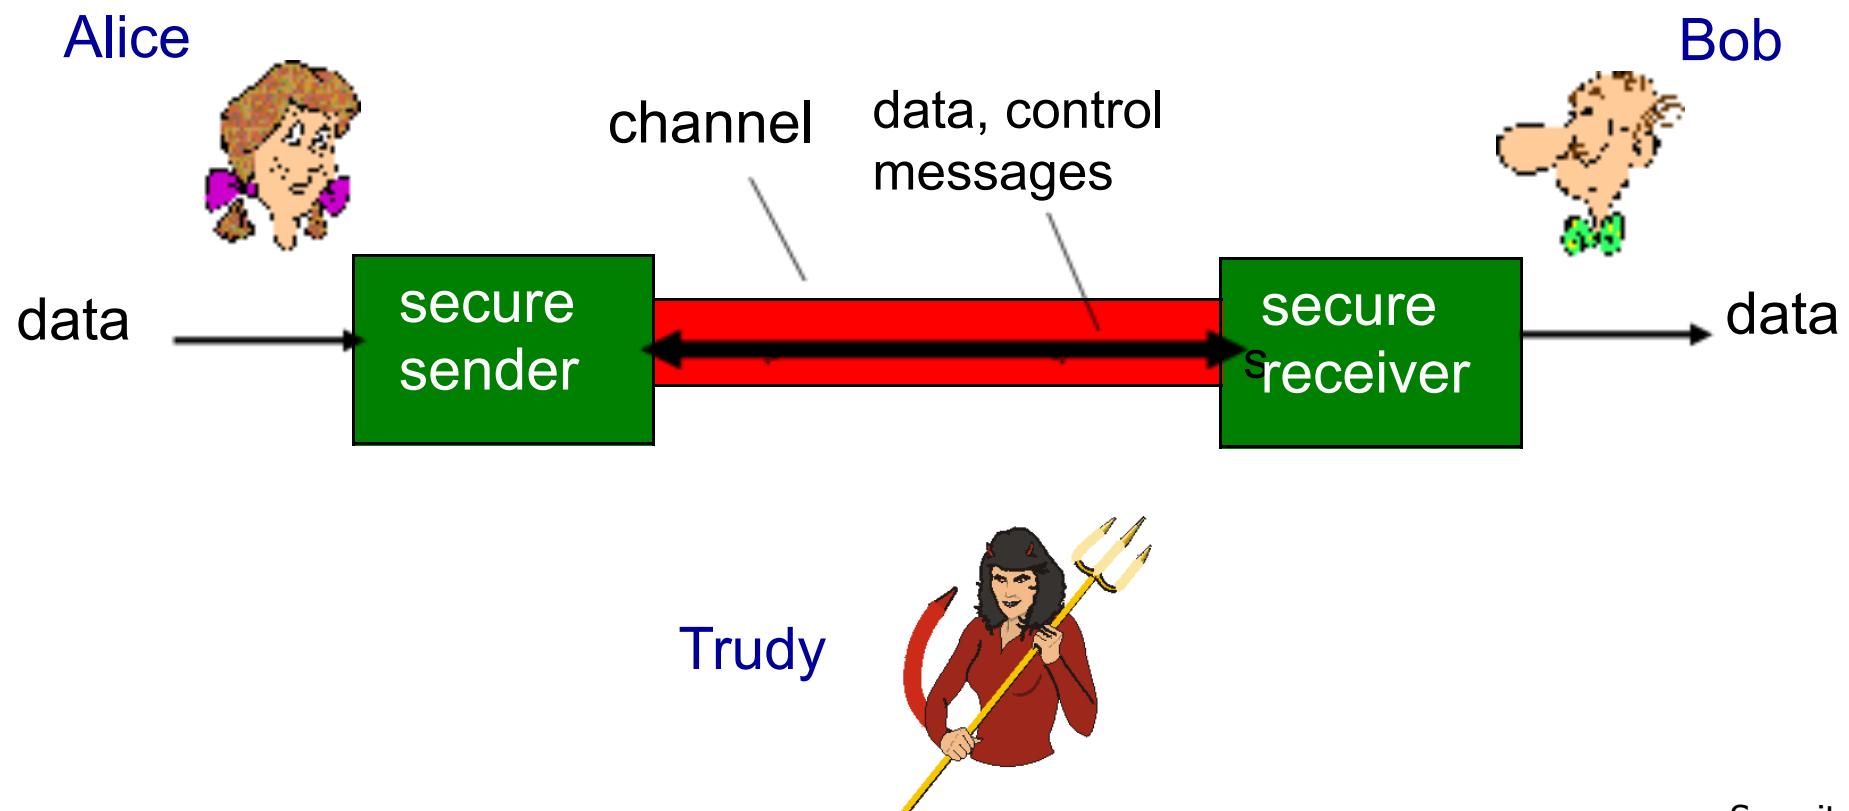

authentication: sender, receiver want to confirm identity of each other

message integrity: sender, receiver want to ensure message not altered (in transit, or afterwards) without detection

access and availability: services must be accessible and available to users

Friends and enemies: Alice, Bob, Trudy

- well-known in network security world
- Bob, Alice (lovers!) want to communicate “securely”
- Trudy (intruder) may intercept, delete, add messages

Who might Bob, Alice be?

- ... well, *real-life* Bobs and Alices!
- Web browser/server for electronic transactions
(e.g., on-line purchases)
- on-line banking client/server
- DNS servers
- routers exchanging routing table updates
- other examples?

There are bad guys (and girls) out there!

Q: What can a “bad guy” do?

A: A lot!

- *eavesdrop*: intercept messages
- actively *insert* messages into connection
- *impersonation*: can fake (spoof) source address in packet (or any field in packet)
- *hijacking*: “take over” ongoing connection by removing sender or receiver, inserting himself in place
- *denial of service*: prevent service from being used by others (e.g., by overloading resources)

Chapter 8 roadmap

8.1 What is network security?

8.2 Principles of cryptography

8.3 Message integrity, authentication

8.4 Securing e-mail

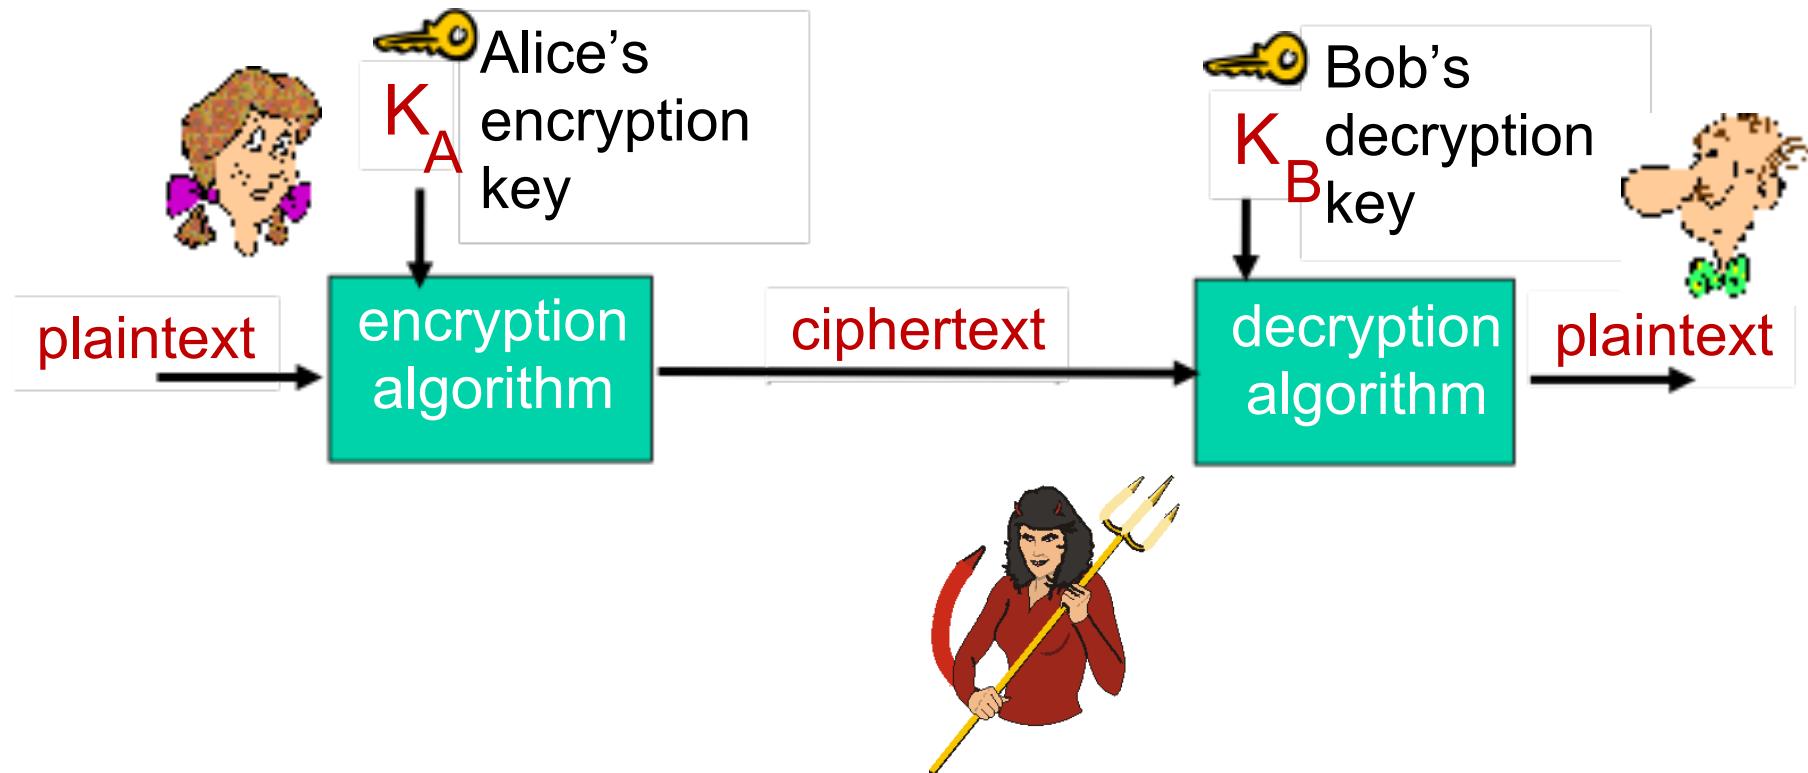

8.5 Securing TCP connections: SSL

8.6 Network layer security: IPsec

8.7 Securing wireless LANs

8.8 Operational security: firewalls and IDS

The language of cryptography

m plaintext message

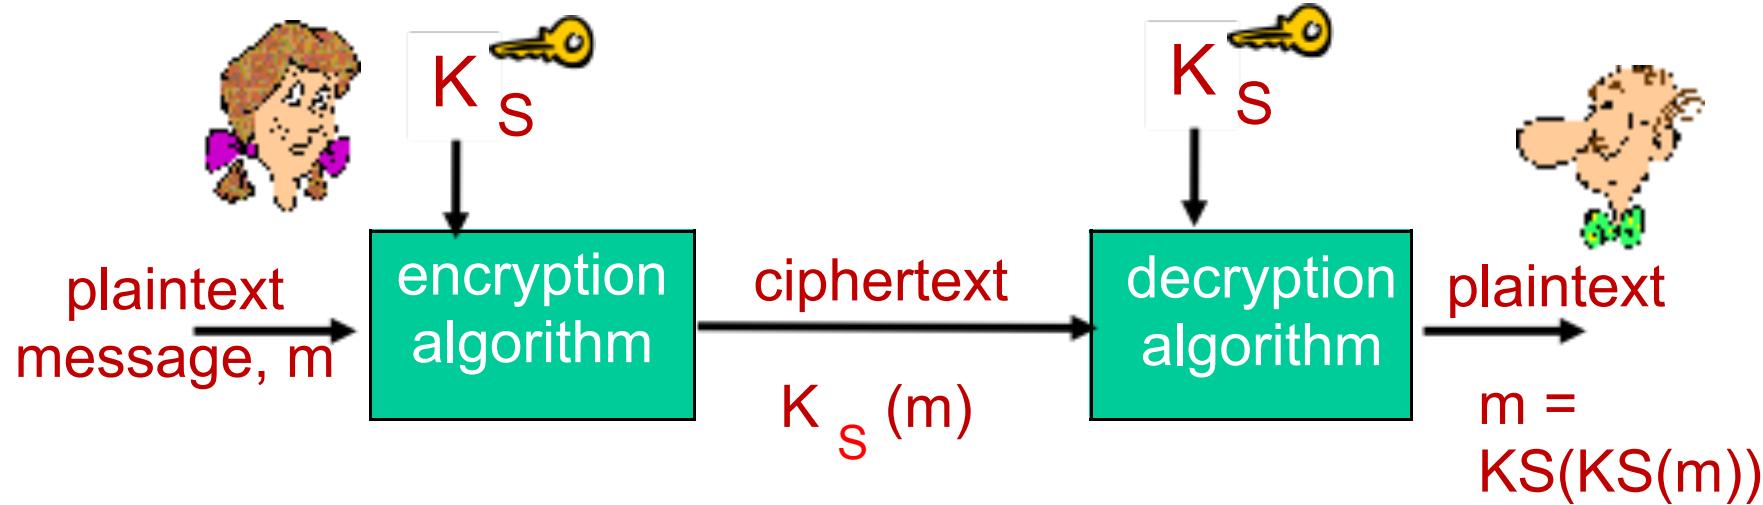

$K_A(m)$ ciphertext, encrypted with key K_A

$m = K_B(K_A(m))$

Breaking an encryption scheme

- **cipher-text only attack:**
Trudy has ciphertext she can analyze
- **two approaches:**
 - brute force: search through all keys
 - statistical analysis
- **known-plaintext attack:**
Trudy has plaintext corresponding to ciphertext
 - e.g., in monoalphabetic cipher, Trudy determines pairings for a,l,i,c,e,b,o,
- **chosen-plaintext attack:**
Trudy can get ciphertext for chosen plaintext

Symmetric key cryptography

symmetric key crypto: Bob and Alice share same (symmetric) key: K_S

- e.g., key is knowing substitution pattern in mono alphabetic substitution cipher

Q: how do Bob and Alice agree on key value?

Simple encryption scheme

substitution cipher: substituting one thing for another

- monoalphabetic cipher: substitute one letter for another

plaintext: abcdefghijklmnopqrstuvwxyz

ciphertext: mnbvcxzasdfghjklpoiuytrewq

e.g.: **Plaintext:** bob. i love you. alice

ciphertext: nkn. s gktc wky. mgsbc

Encryption key: mapping from set of 26 letters
to set of 26 letters

A more sophisticated encryption approach

- n substitution ciphers, M_1, M_2, \dots, M_n
- cycling pattern:
 - e.g., $n=4$: $M_1, M_3, M_4, M_3, M_2; M_1, M_3, M_4, M_3, M_2; \dots$
- for each new plaintext symbol, use subsequent substitution pattern in cyclic pattern
 - dog: d from M_1 , o from M_3 , g from M_4

Encryption key: n substitution ciphers, and cyclic pattern

Symmetric key crypto: DES

DES: Data Encryption Standard

- US encryption standard [NIST 1993]
- 56-bit symmetric key, 64-bit plaintext input
- block cipher with cipher block chaining
- how secure is DES?
 - DES Challenge: 56-bit-key-encrypted phrase decrypted (brute force) in less than a day
- making DES more secure:
 - 3DES: encrypt 3 times with 3 different keys

AES: Advanced Encryption Standard

- symmetric-key NIST standard, replaced DES (Nov 2001)
- processes data in 128 bit blocks
- 128, 192, or 256 bit keys
- brute force decryption (try each key) taking 1 sec on DES, takes 149 trillion years for AES

Public Key Cryptography

symmetric key crypto

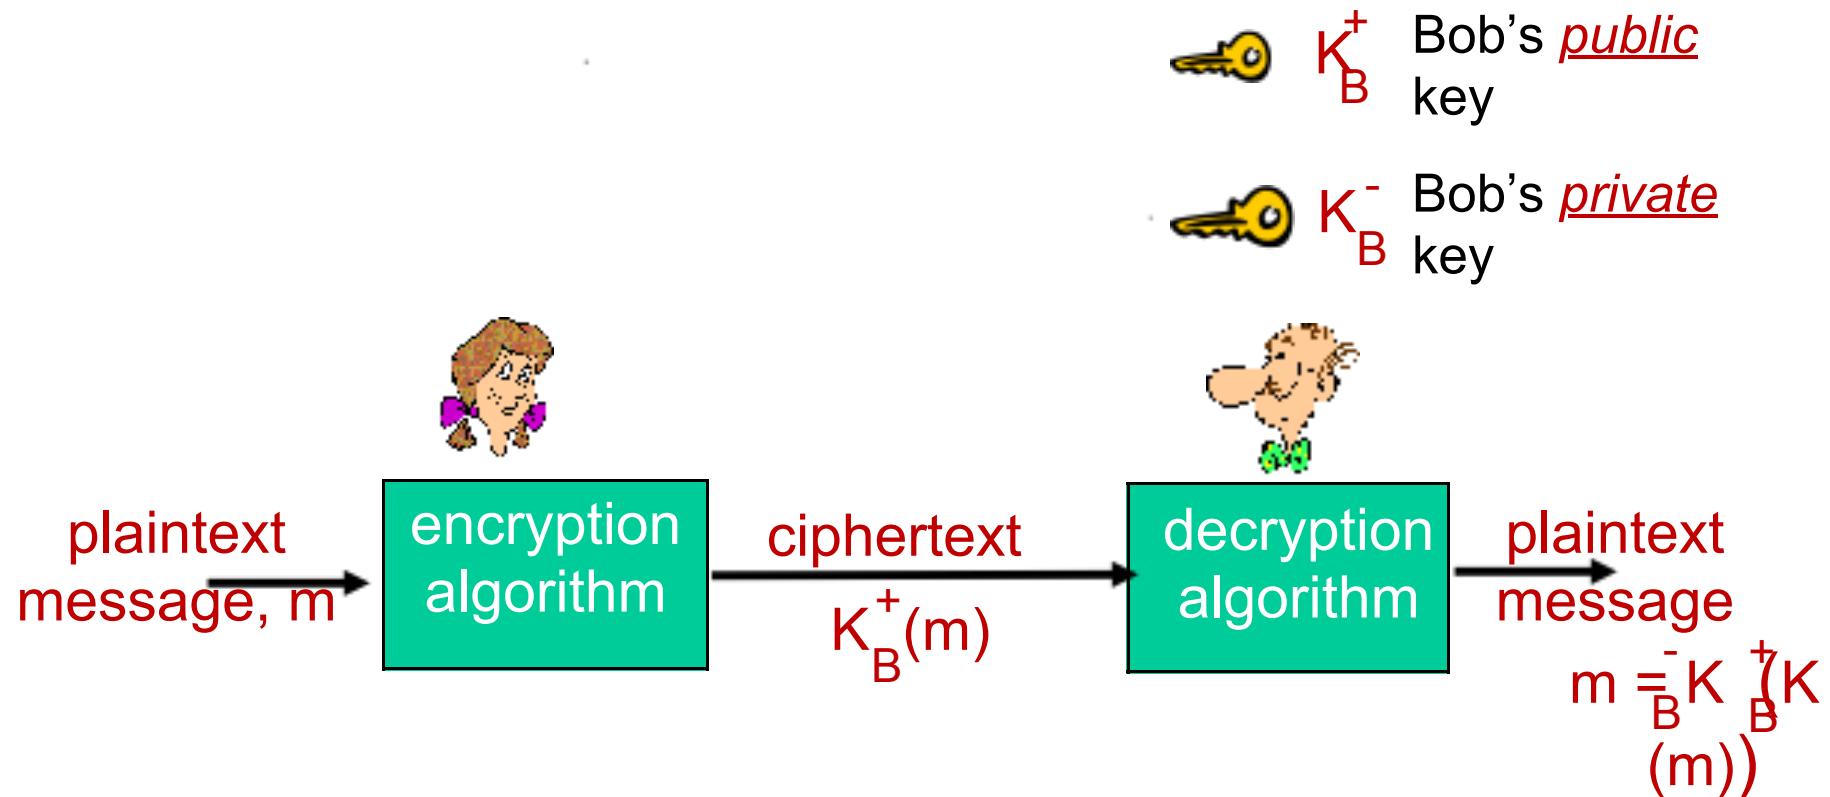

- requires sender, receiver know shared secret key
- Q: how to agree on key in first place (particularly if never “met”)?

public key crypto

- radically different approach [Diffie-Hellman76, RSA78]
- sender, receiver do *not* share secret key
- *public* encryption key known to *all*
- *private* decryption key known only to receiver

Public key cryptography

Public key encryption algorithms

requirements:

- ① need $K_B^+(\cdot)$ and $K_B^-(\cdot)$ such that

$$K_B^-(K_B^+(m)) = m$$

- ② given public key K_B^+ , it should be impossible to compute private key K_B^-

RSA: Rivest, Shamir, Adelson
algorithm

RSA: another important property

The following property will be *very* useful later:

$$K_B^-(K_B^+(m)) = m = K_B^+(K_B^-(m))$$

use public key
first, followed by
private key

use private key
first, followed by
public key

result is the same!

RSA in practice: session keys

- exponentiation in RSA is computationally intensive
- DES is at least 100 times faster than RSA
- use public key crypto to establish secure connection, then establish second key – symmetric session key – for encrypting data

session key, KS

- Bob and Alice use RSA to exchange a symmetric key KS
- once both have KS, they use symmetric key cryptography

Chapter 8 roadmap

- 8.1 What is network security?
- 8.2 Principles of cryptography
- 8.3 Message integrity, *authentication*
- 8.4 Securing e-mail
- 8.5 Securing TCP connections: SSL
- 8.6 Network layer security: IPsec
- 8.7 Securing wireless LANs
- 8.8 Operational security: firewalls and IDS

Authentication

Goal: Bob wants Alice to “prove” her identity to him

Protocol apl.0: Alice says “I am Alice”

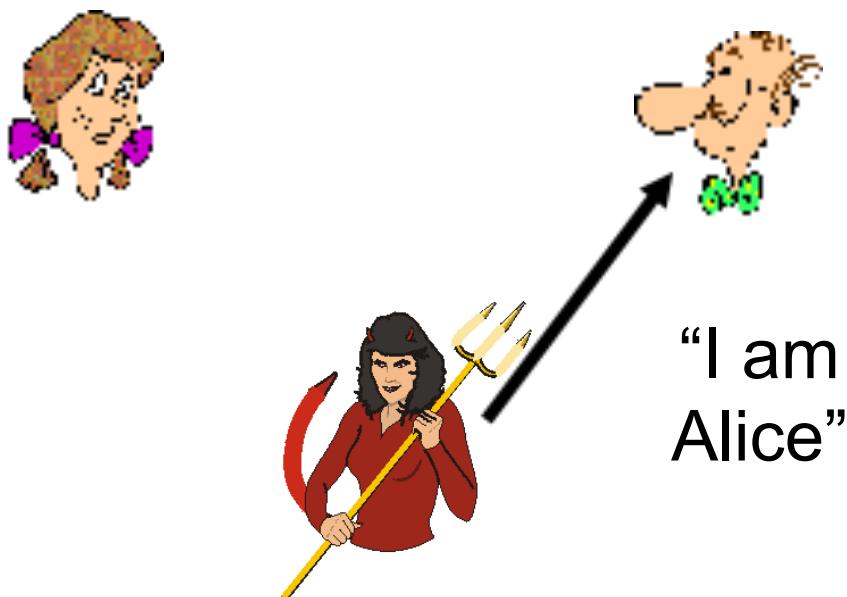

Failure scenario??

Authentication

Goal: Bob wants Alice to “prove” her identity to him

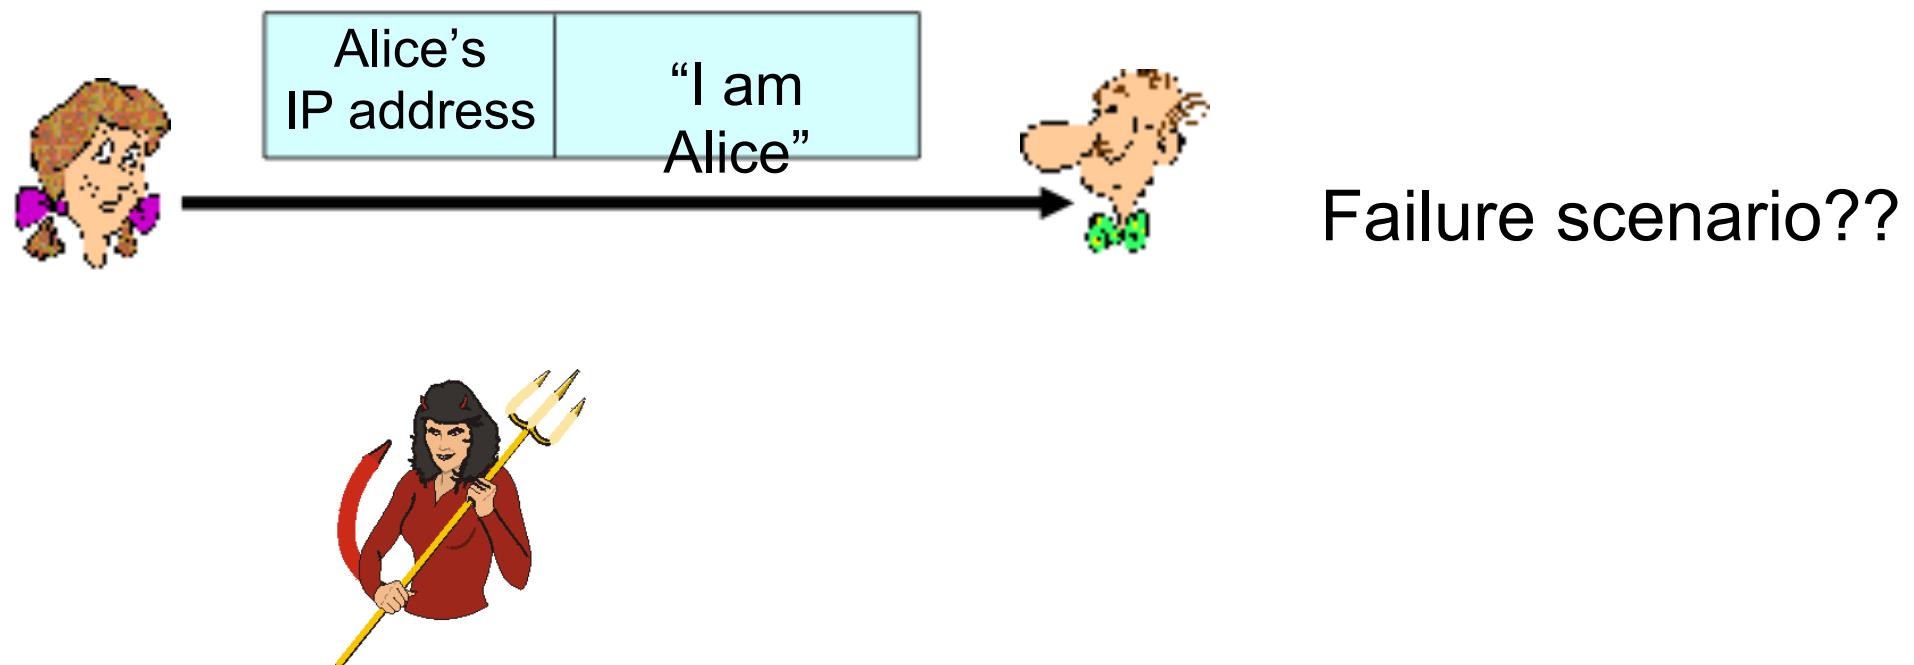

Protocol apl.0: Alice says “I am Alice”

in a network,
Bob can not “see” Alice,
so Trudy simply declares
herself to be Alice

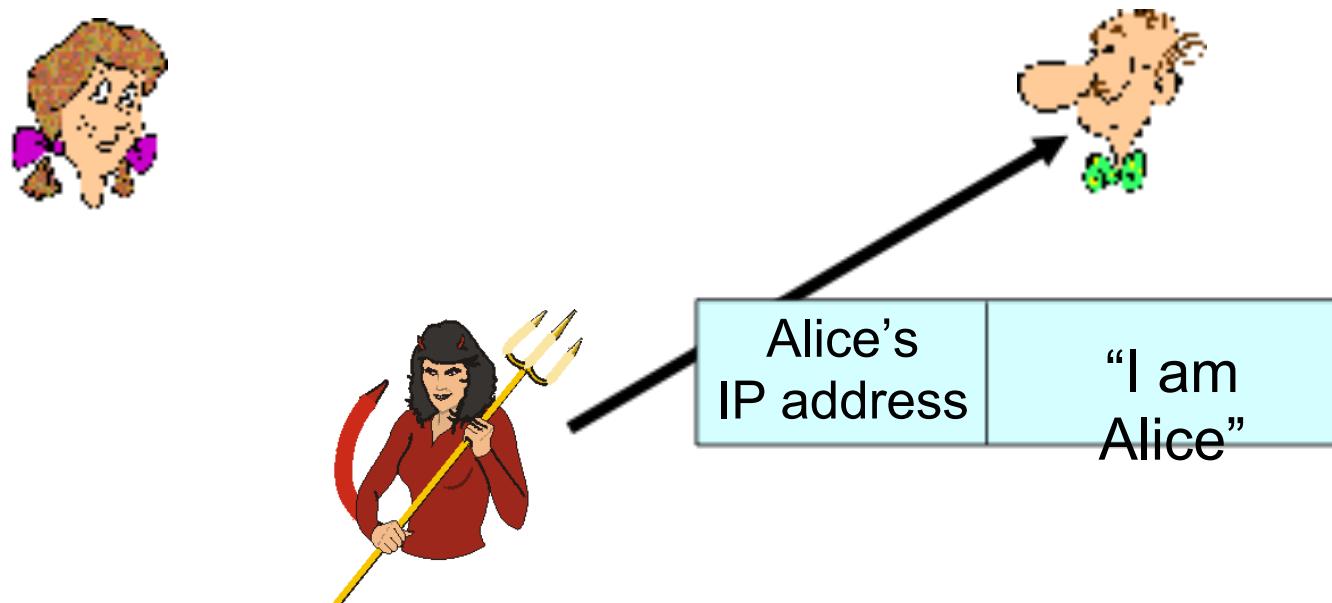

Authentication: another try

Protocol ap2.0: Alice says “I am Alice” in an IP packet containing her source IP address

Authentication: another try

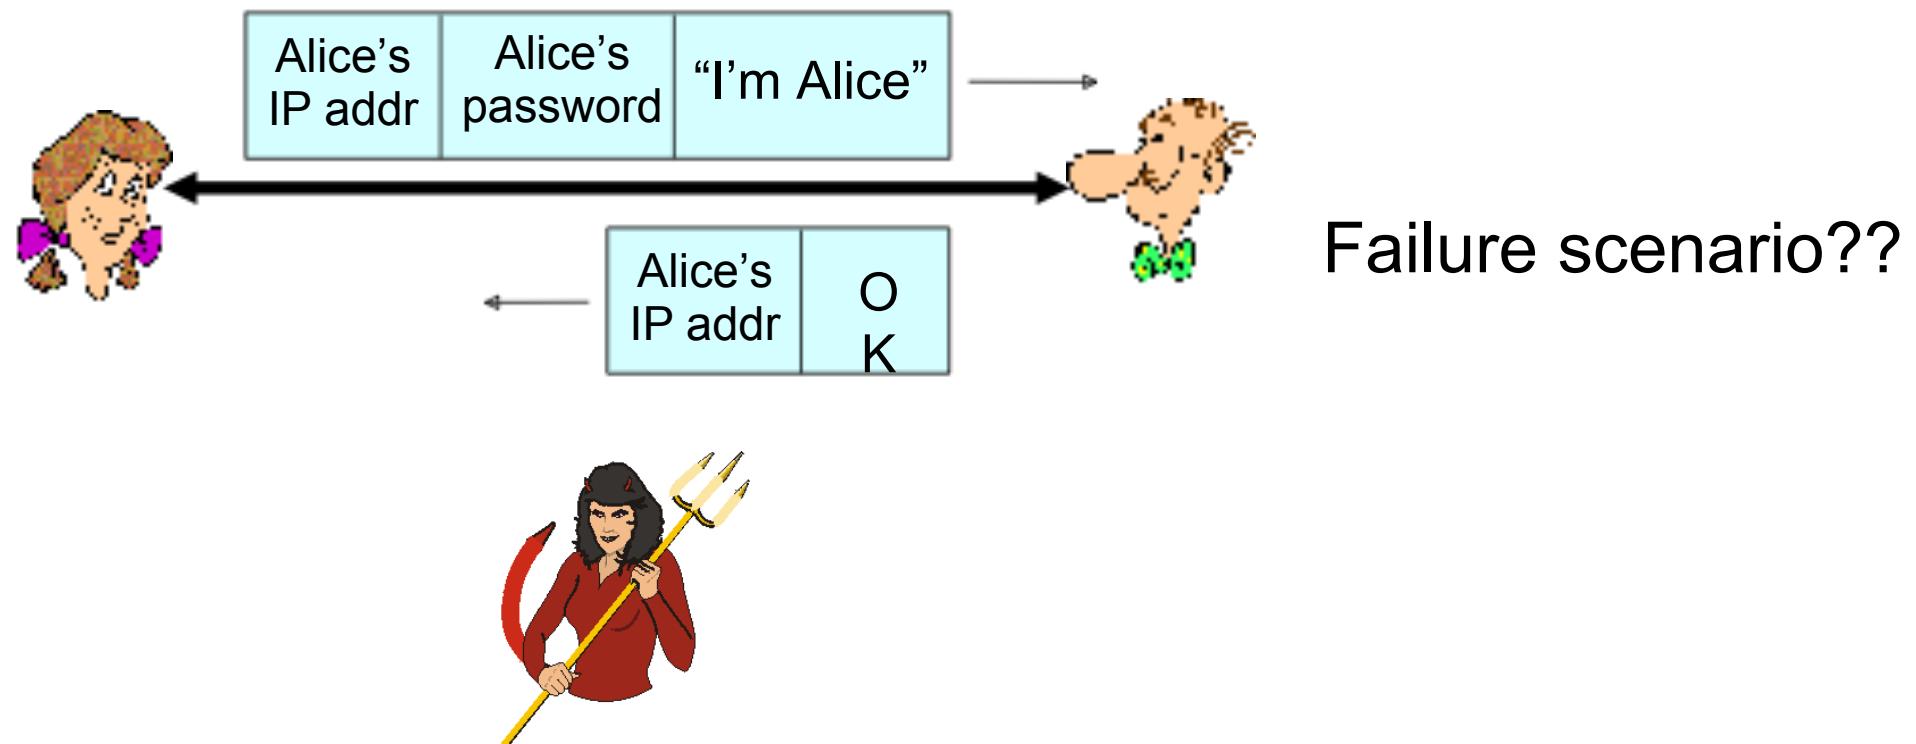

Protocol ap2.0: Alice says “I am Alice” in an IP packet containing her source IP address

Trudy can create
a packet “spoofing”
Alice’s address

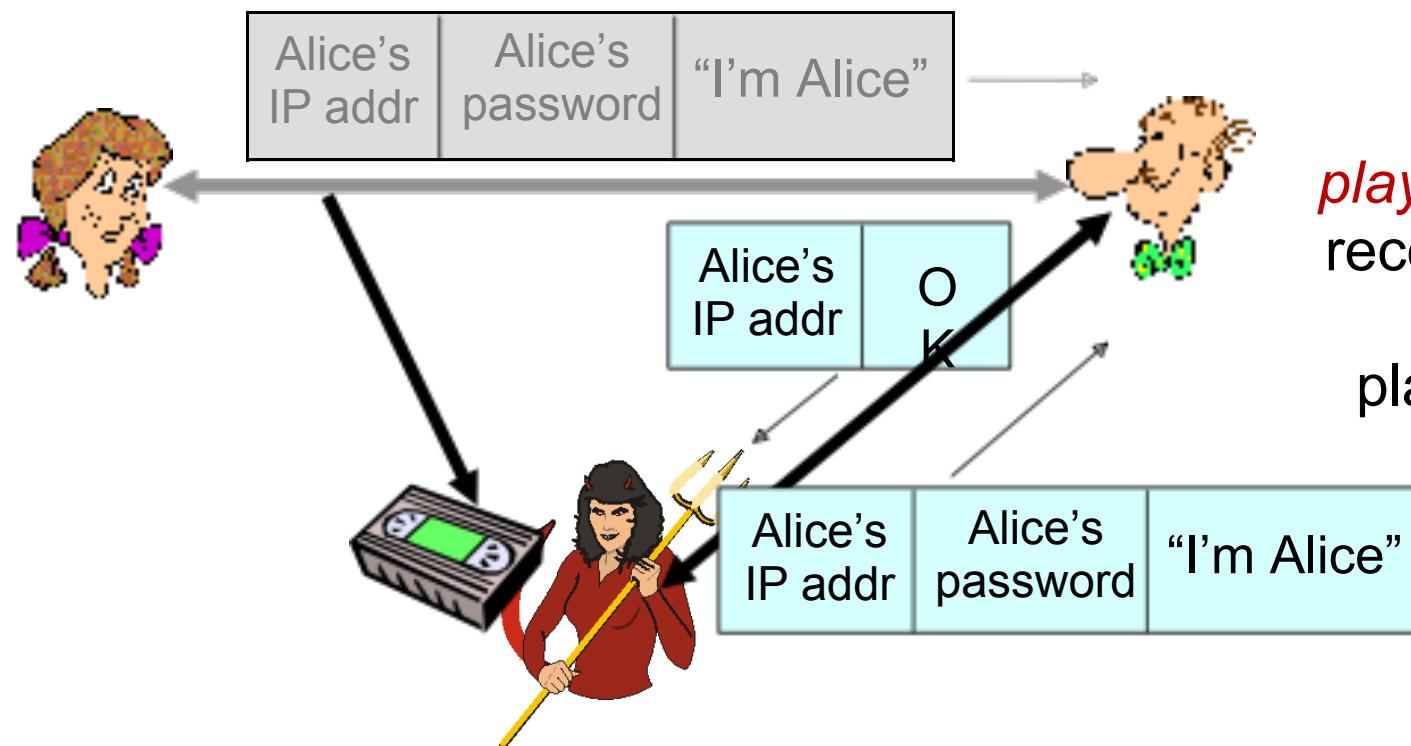

Authentication: another try

Protocol ap3.0: Alice says “I am Alice” and sends her secret password to “prove” it.

Authentication: another try

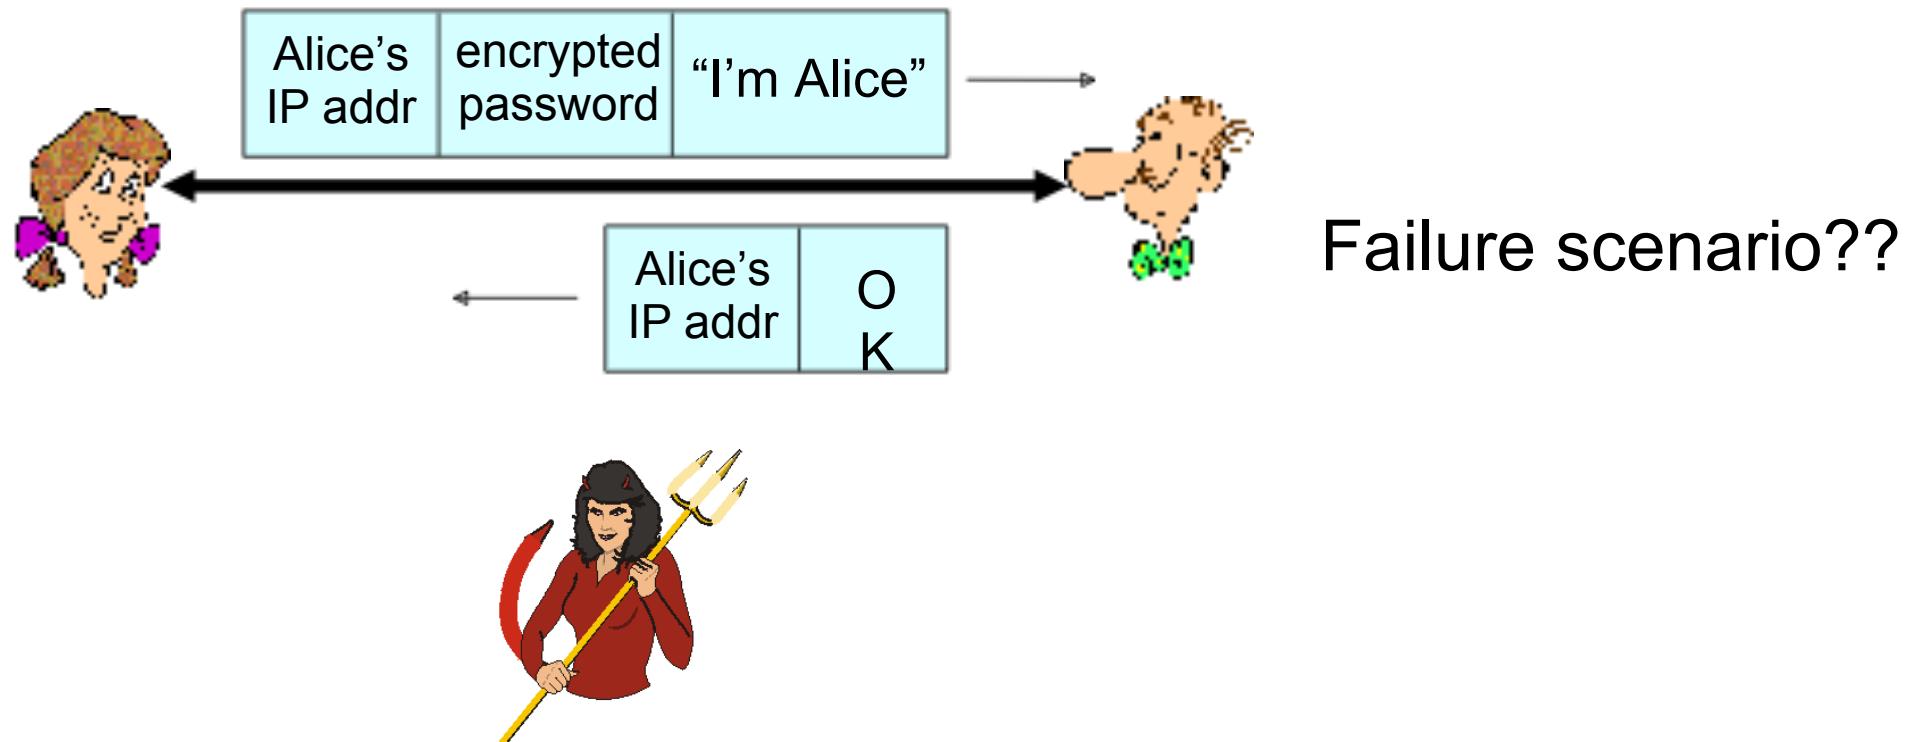

Protocol ap3.0: Alice says “I am Alice” and sends her secret password to “prove” it.

playback attack: Trudy records Alice's packet and later plays it back to Bob

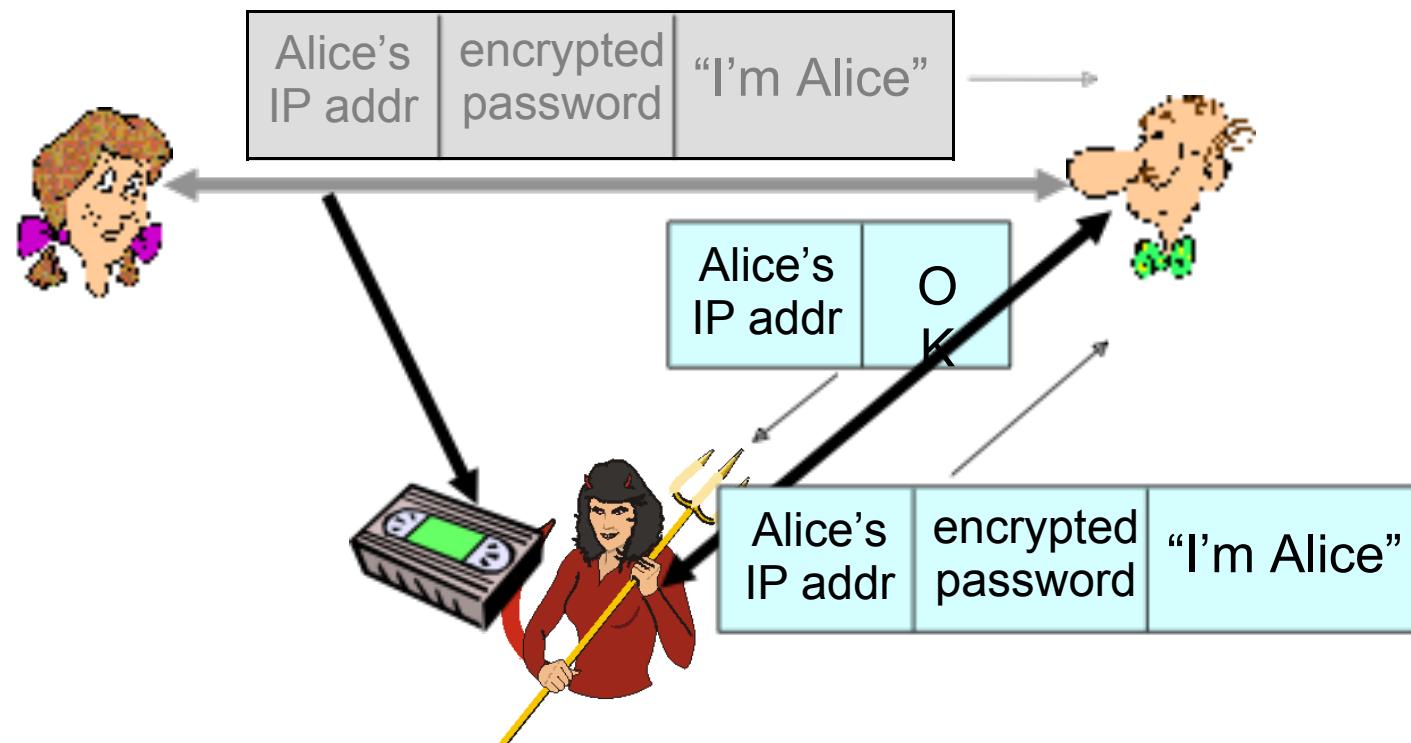

Authentication: yet another try

Protocol ap3.1: Alice says “I am Alice” and sends her *encrypted* secret password to “prove” it.

Authentication: yet another try

Protocol ap3.1: Alice says “I am Alice” and sends her *encrypted* secret password to “prove” it.

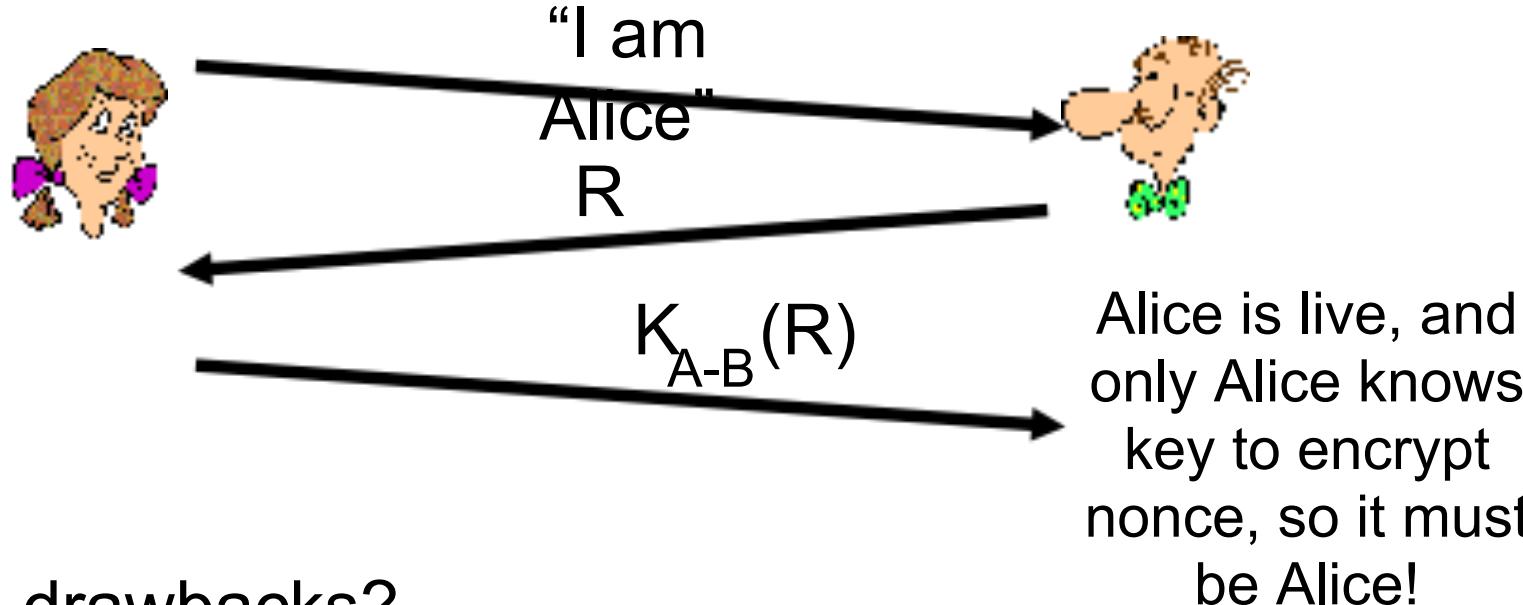

record
and
playback
still works!

Authentication: yet another try

Goal: avoid playback

nonce: number ~~attack~~ used only *once-in-a-*

ap4.0: to prove Alice “live”, Bob sends ~~lifetime~~ Alice *nonce*, R.
Alice
must return R, encrypted with shared secret key

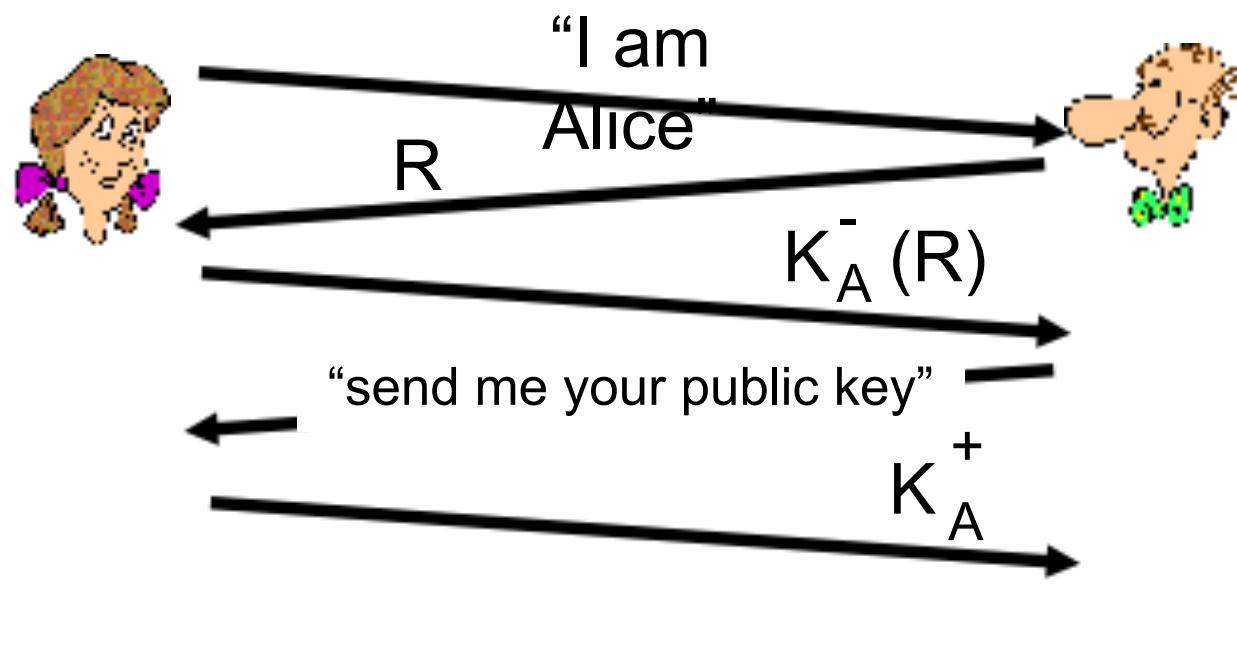

Failures, drawbacks?

Authentication: ap5.0

ap4.0 requires shared symmetric key

- can we authenticate using public key techniques?

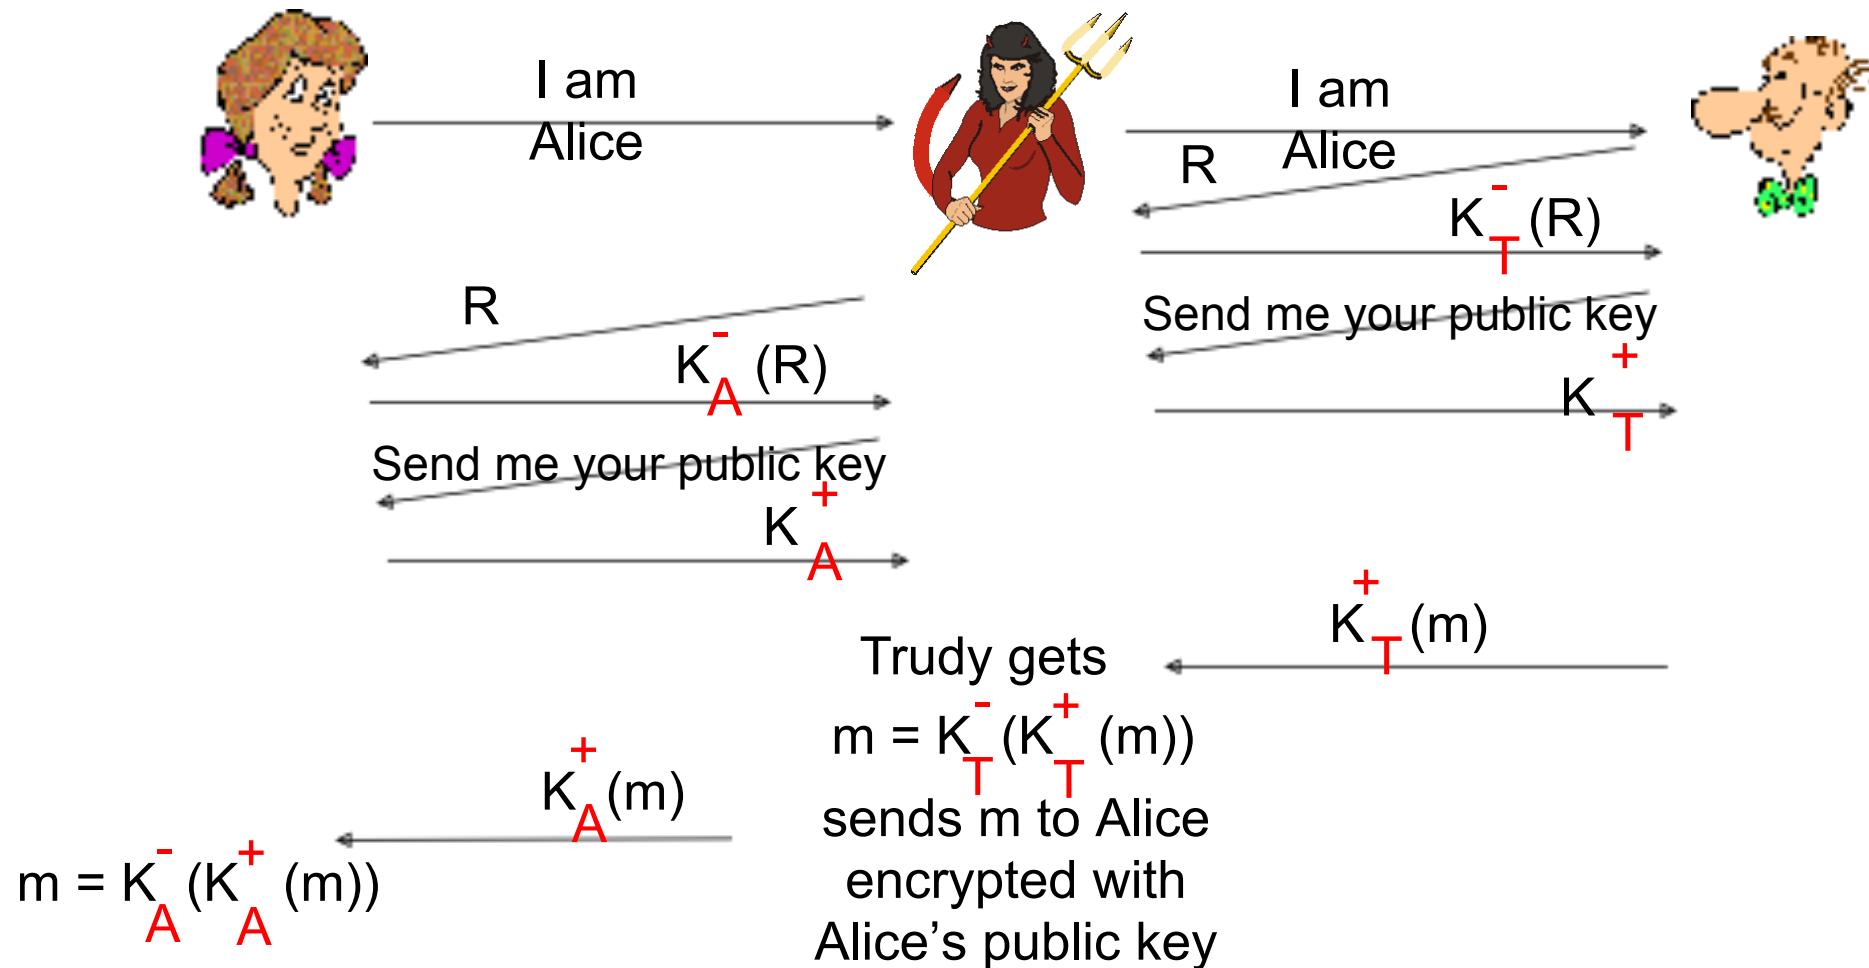

ap5.0: use nonce, public key cryptography

Bob computes
 $K_A^+(K_A^-(R)) = R$
and knows only Alice
could have the private
key, that encrypted R
such that
 $K_A^+(K_A^-(R)) = R$

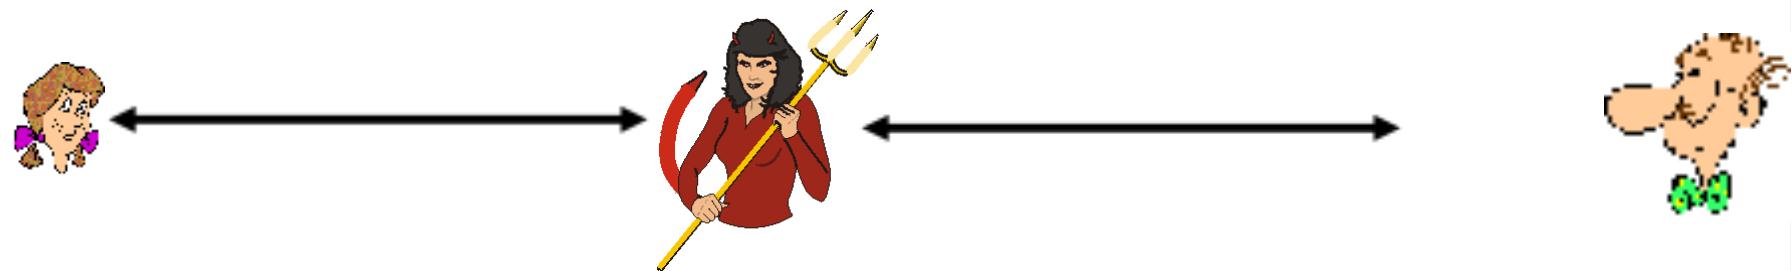

ap5.0: security hole

man (or woman) in the middle attack: Trudy poses as Alice (to Bob) and as Bob (to Alice)

ap5.0: security hole

man (or woman) in the middle attack: Trudy poses as Alice (to Bob) and as Bob (to Alice)

difficult to detect:

- Bob receives everything that Alice sends, and vice versa.
(e.g., so Bob, Alice can meet one week later and recall conversation!)
- problem is that Trudy receives all messages as well!

Chapter 8 roadmap

- 8.1 What is network security?
- 8.2 Principles of cryptography
- 8.3 *Message integrity*, authentication
- 8.4 Securing e-mail
- 8.5 Securing TCP connections: SSL
- 8.6 Network layer security: IPsec
- 8.7 Securing wireless LANs
- 8.8 Operational security: firewalls and IDS

Digital signatures

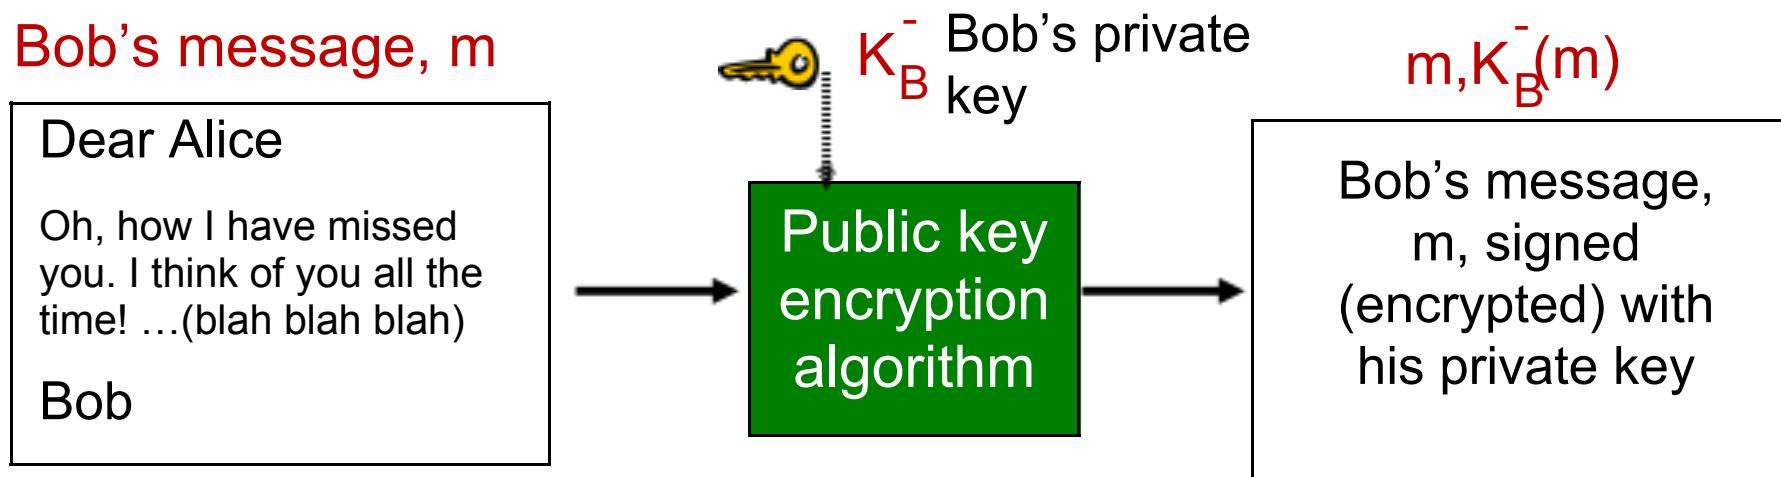

cryptographic technique analogous to hand-written signatures:

- sender (Bob) digitally signs document, establishing he is document owner/creator.
- *verifiable, nonforgeable*: recipient (Alice) can prove to someone that Bob, and no one else (including Alice), must have signed document

Digital signatures

simple digital signature for message m :

- Bob signs m by encrypting with his private key K_B , creating “signed” message, $K_B(m)$

Digital signatures

- suppose Alice receives msg m , with signature: $m, \bar{K}B(m)$
- Alice verifies m signed by Bob by applying Bob's public key $\bar{K}B^\dagger$ to $\bar{K}B(m)$ then checks $\bar{K}B^\dagger(\bar{K}B(m)) = m$.
- If $\bar{K}B^\dagger(\bar{K}B(m)) = m$, whoever signed m must have used Bob's private key.

Alice thus verifies that:

- Bob signed m
- no one else signed m
- Bob signed m and not m'

non-repudiation:

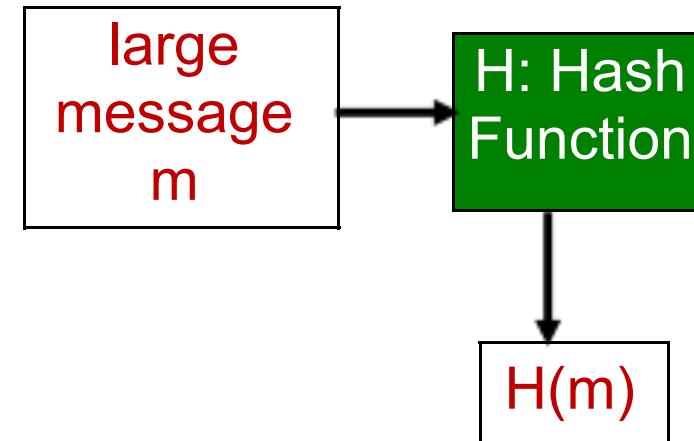

- Alice can take m , and signature $\bar{K}B(m)$ to court and prove that Bob signed m

Message digests

computationally expensive to public-key-encrypt long messages

goal: fixed-length, easy-to-compute digital “fingerprint”

- apply hash function H to m , get fixed size message digest, $H(m)$.

Hash function properties:

- many-to-1
- produces fixed-size msg digest (fingerprint)
- given message digest x , computationally infeasible to find m such that $x = H(m)$

Internet checksum: poor crypto hash function

Internet checksum has some properties of hash function:

- produces fixed length digest (16-bit sum) of message
- is many-to-one

But given message with given hash value, it is easy to find another message with same hash value:

<u>message</u>	<u>ASCII format</u>
I O U 1	49 4F 55 31
0 0 . 9	30 30 2E 39
9 B O B	39 42 D2 42

<u>message</u>	<u>ASCII format</u>
I O U 9	49 4F 55 <u>39</u>
0 0 . 1	30 30 2E <u>31</u>
9 B O B	39 42 D2 42

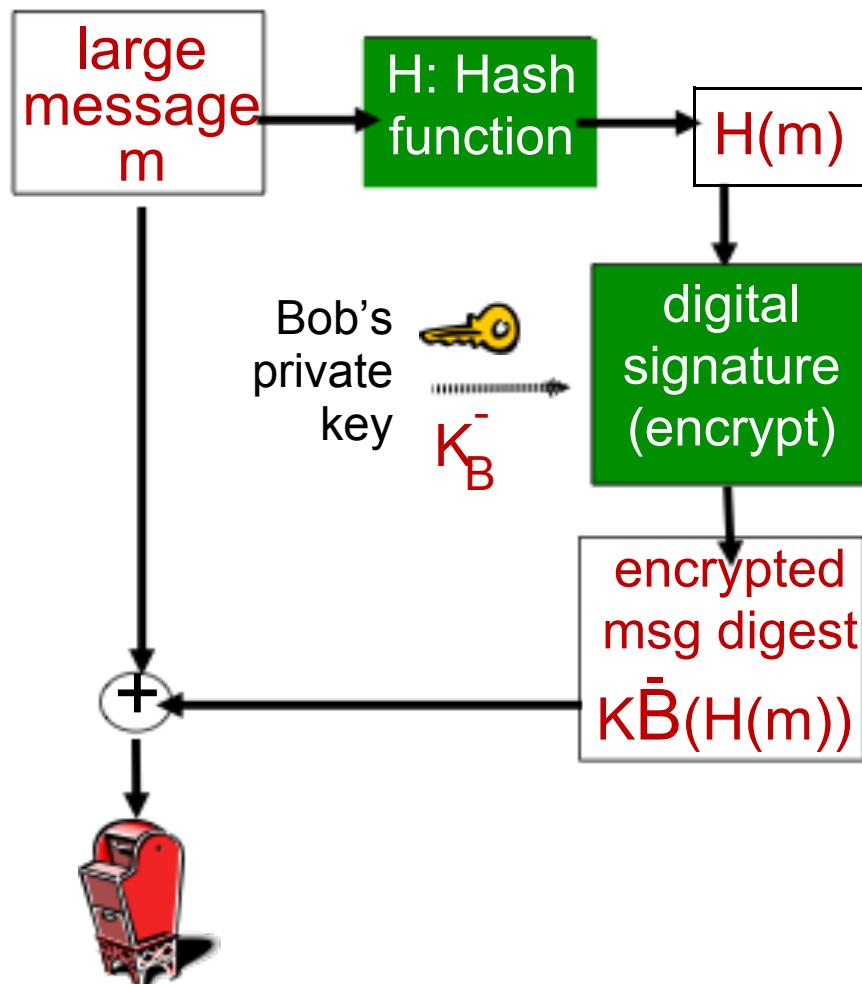

B2 C1 D2 AC

different messages
but identical checksums!

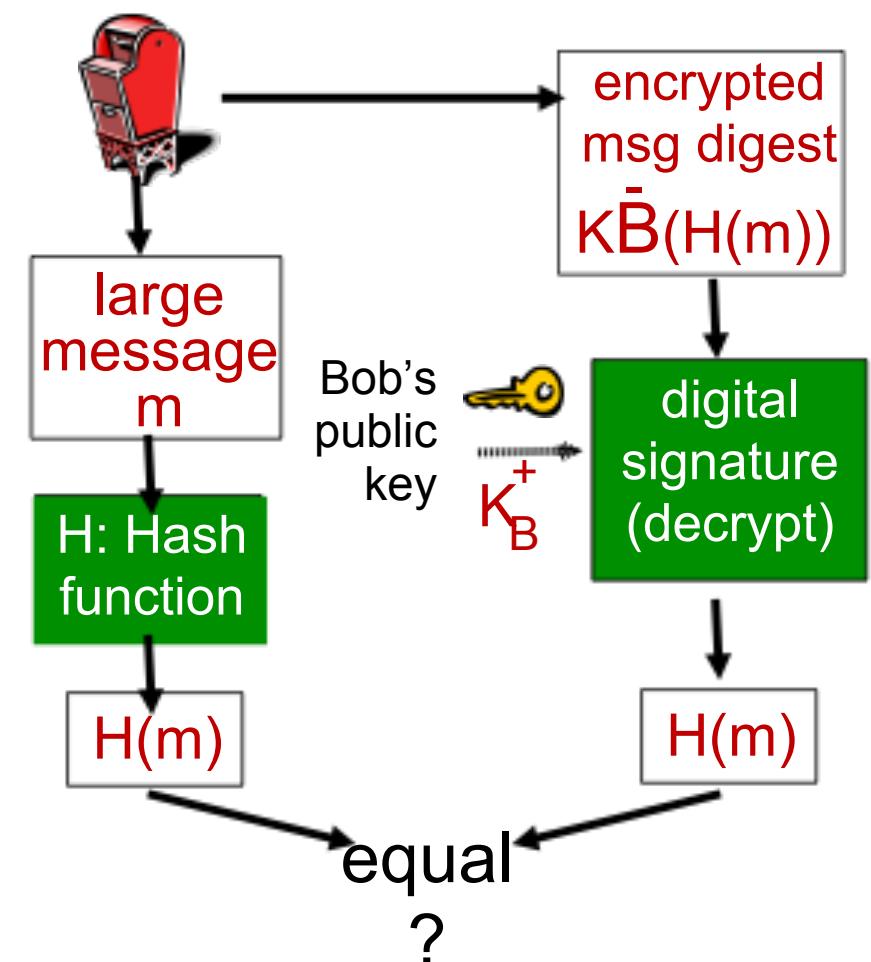

B2 C1 D2 AC

Digital signature = signed message digest

Bob sends digitally signed message:

Alice verifies signature, integrity of digitally signed message:

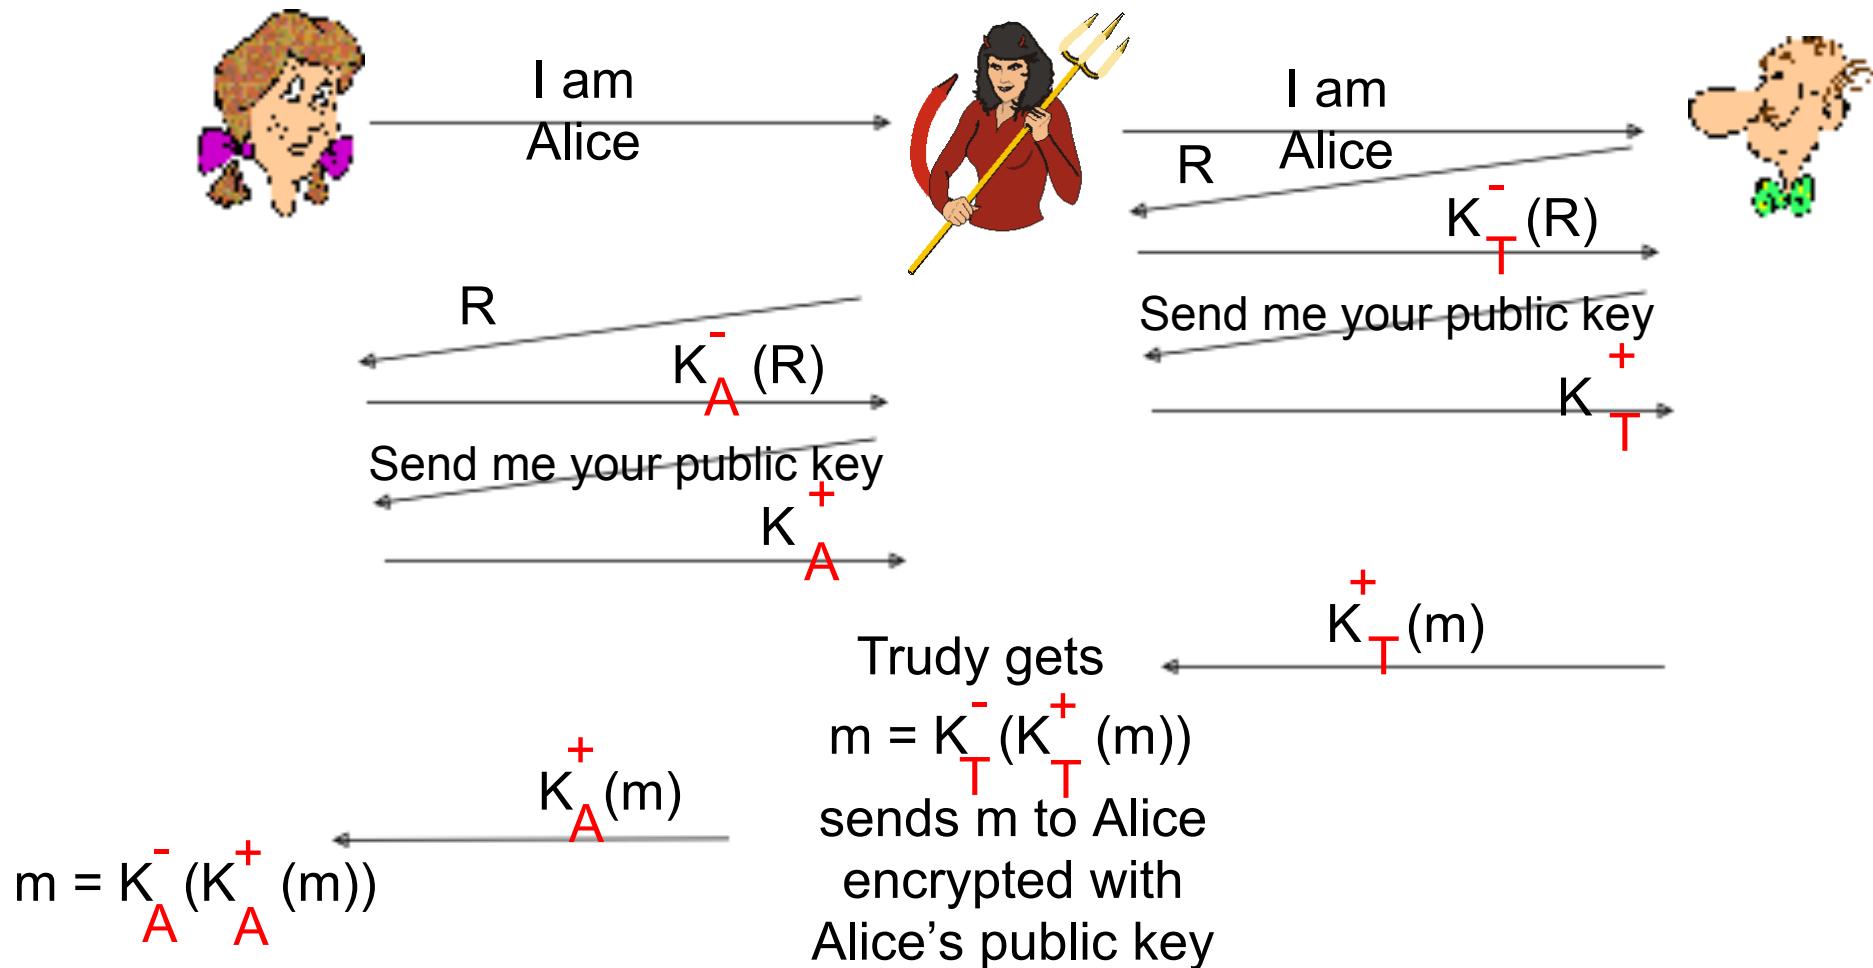

Hash function algorithms

- MD5 hash function widely used (RFC 1321)
 - computes 128-bit message digest in 4-step process.
 - arbitrary 128-bit string x , appears difficult to construct msg m whose MD5 hash is equal to x
- SHA-1 is also used
 - US standard [NIST, FIPS PUB 180-1]
 - 160-bit message digest

Recall: ap5.0 security hole

man (or woman) in the middle attack: Trudy poses as Alice (to Bob) and as Bob (to Alice)

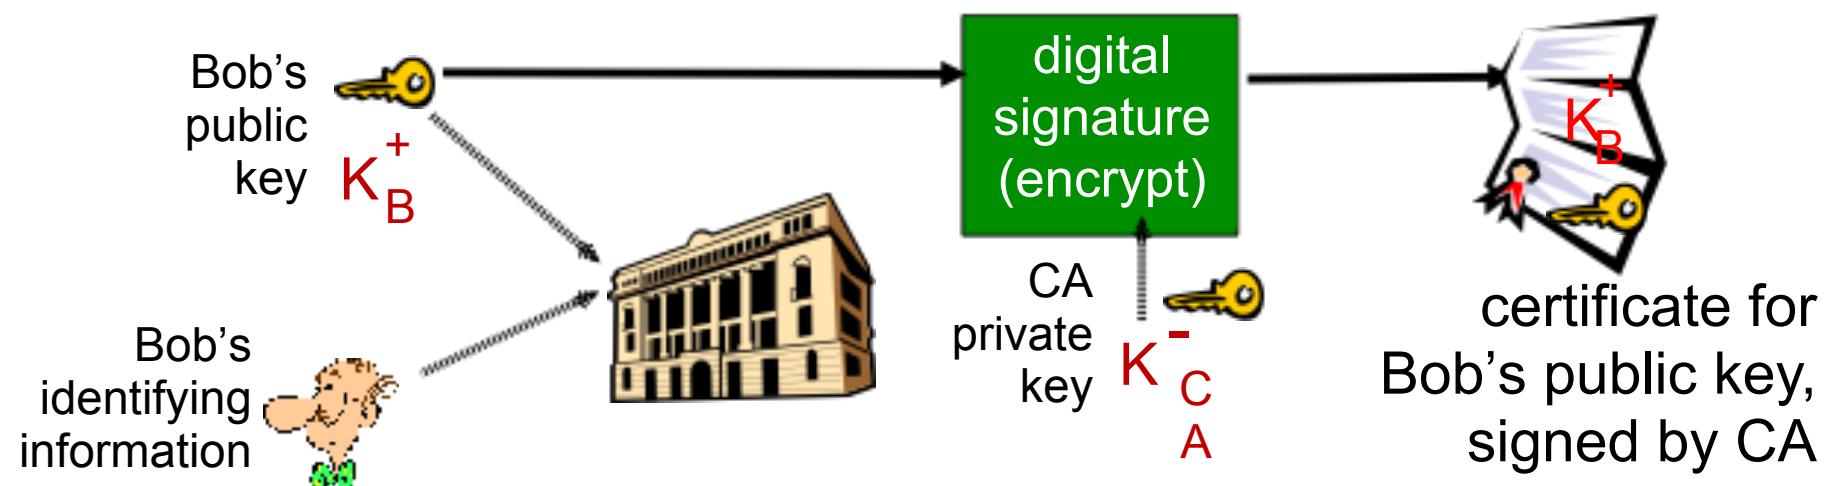

Public-key certification

- motivation: Trudy plays pizza prank on Bob
 - Trudy creates e-mail order:
Dear Pizza Store, Please deliver to me four pepperoni pizzas. Thank you, Bob
 - Trudy signs order with her private key
 - Trudy sends order to Pizza Store
 - Trudy sends to Pizza Store her public key, but says it's Bob's public key
 - Pizza Store verifies signature; then delivers four pepperoni pizzas to Bob
 - Bob doesn't even like pepperoni

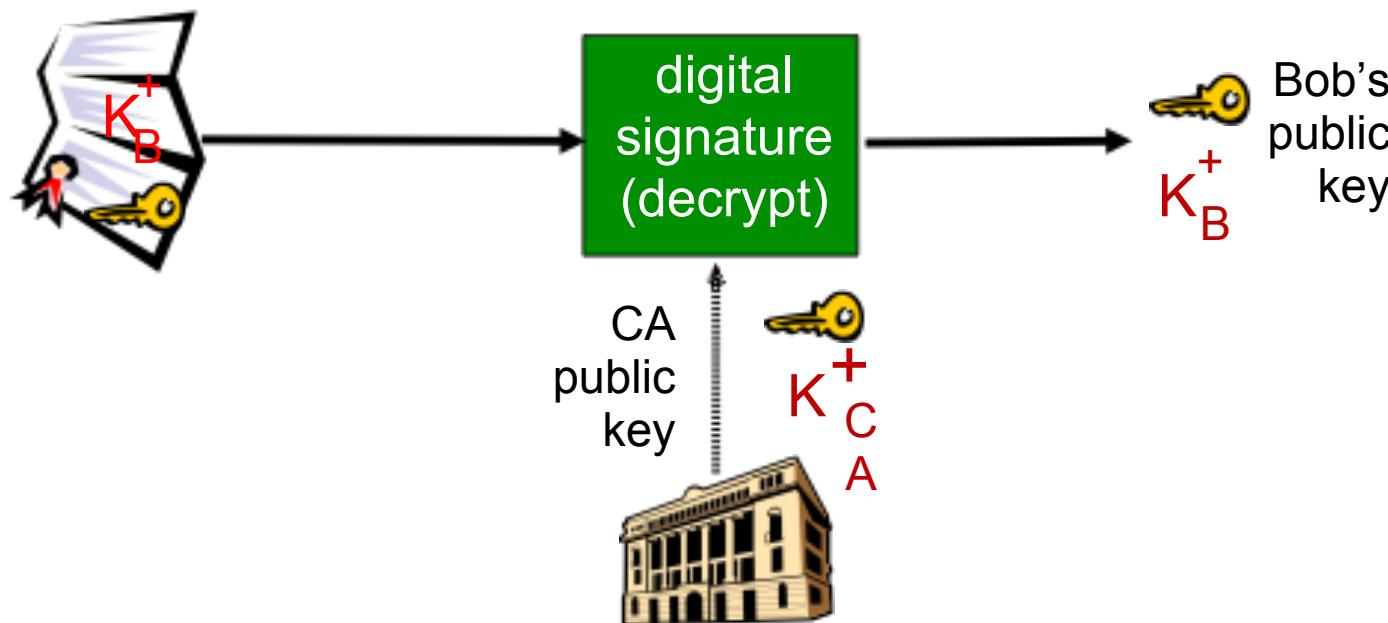

Certification authorities

- *certification authority (CA)*: binds public key to particular entity, E.
- E (person, router) registers its public key with CA.
 - E provides “proof of identity” to CA.
 - CA creates certificate binding E to its public key.
 - certificate containing E’s public key digitally signed by CA – CA says “this is E’s public key”

Certification authorities

- when Alice wants Bob's public key:
 - gets Bob's certificate (Bob or elsewhere).
 - apply CA's public key to Bob's certificate, get Bob's public key

Chapter 8 roadmap

8.1 What is network security?

8.2 Principles of cryptography

8.3 Message integrity, authentication

8.4 Securing e-mail

8.5 Securing TCP connections: SSL

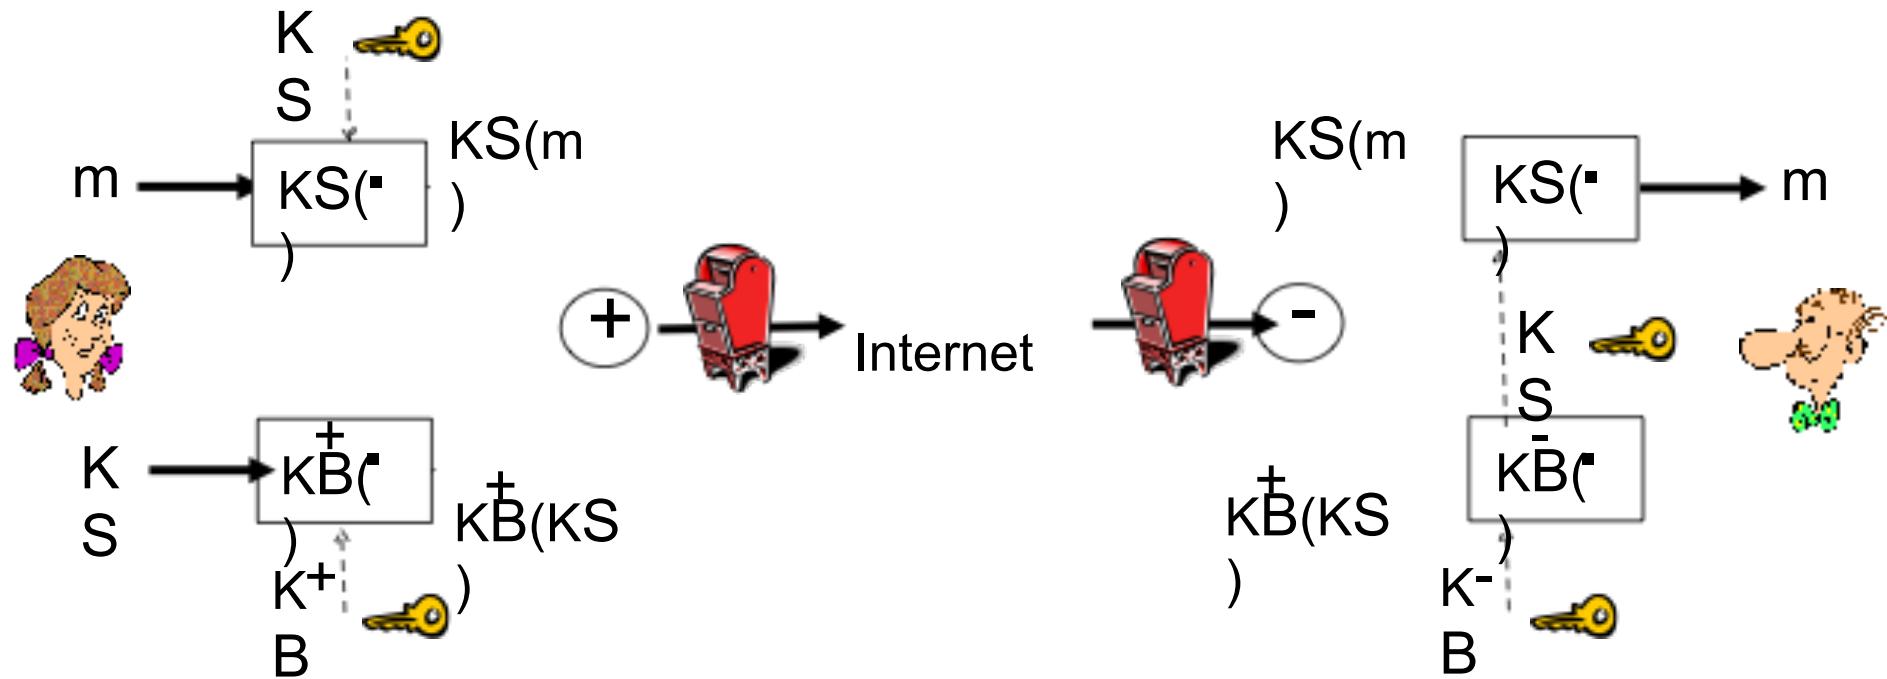

8.6 Network layer security: IPsec

8.7 Securing wireless LANs

8.8 Operational security: firewalls and IDS

Secure e-mail

Alice wants to send confidential e-mail, m , to Bob.

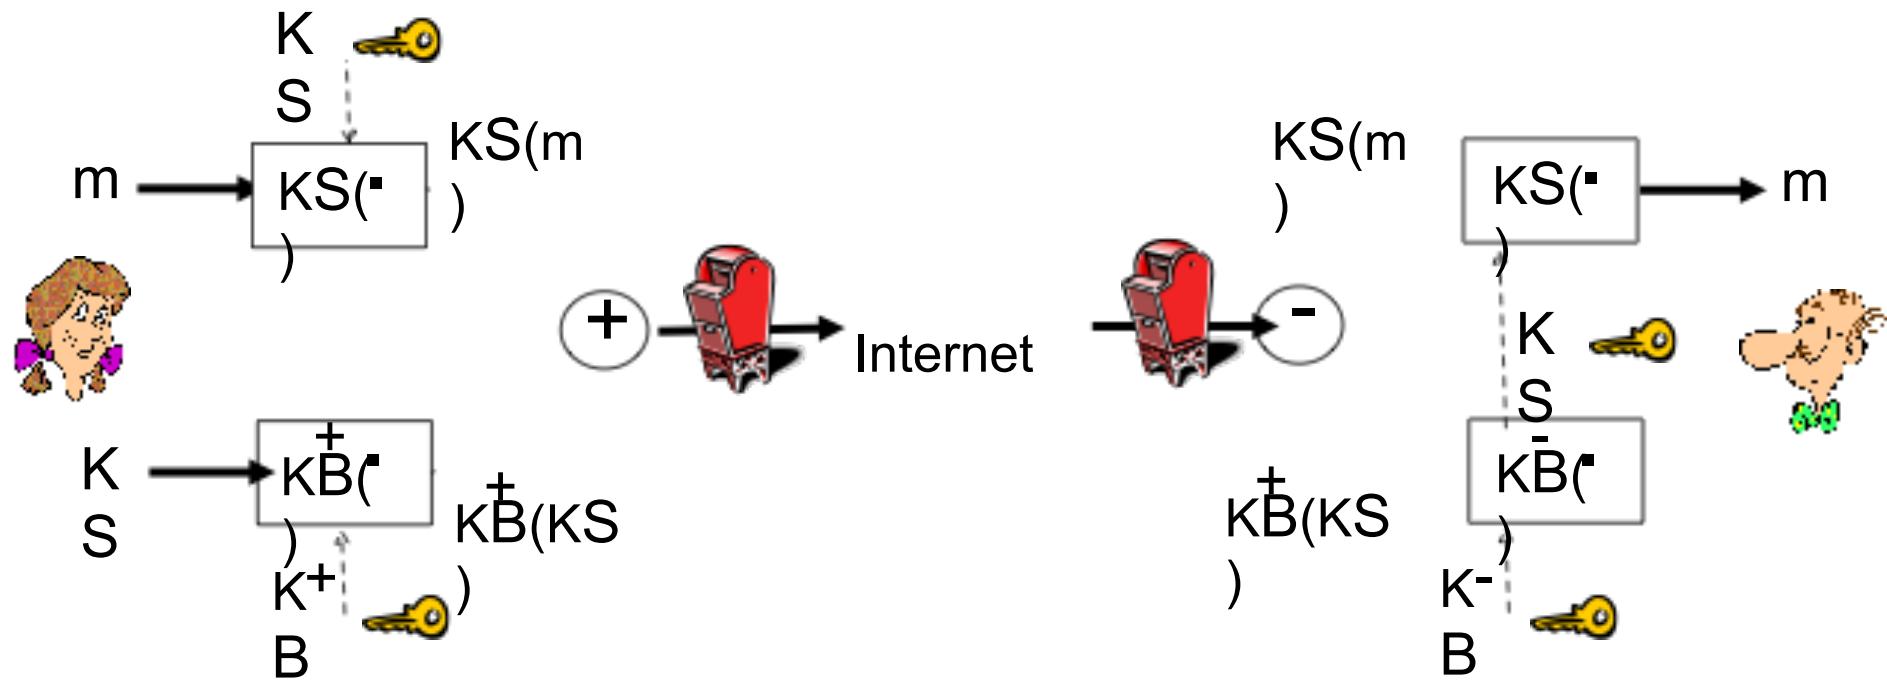

Alice:

- generates random *symmetric* private key, KS
- encrypts message with KS (for efficiency)
- also encrypts KS with Bob's public key

Secure e-mail

Alice wants to send confidential e-mail, m , to Bob.

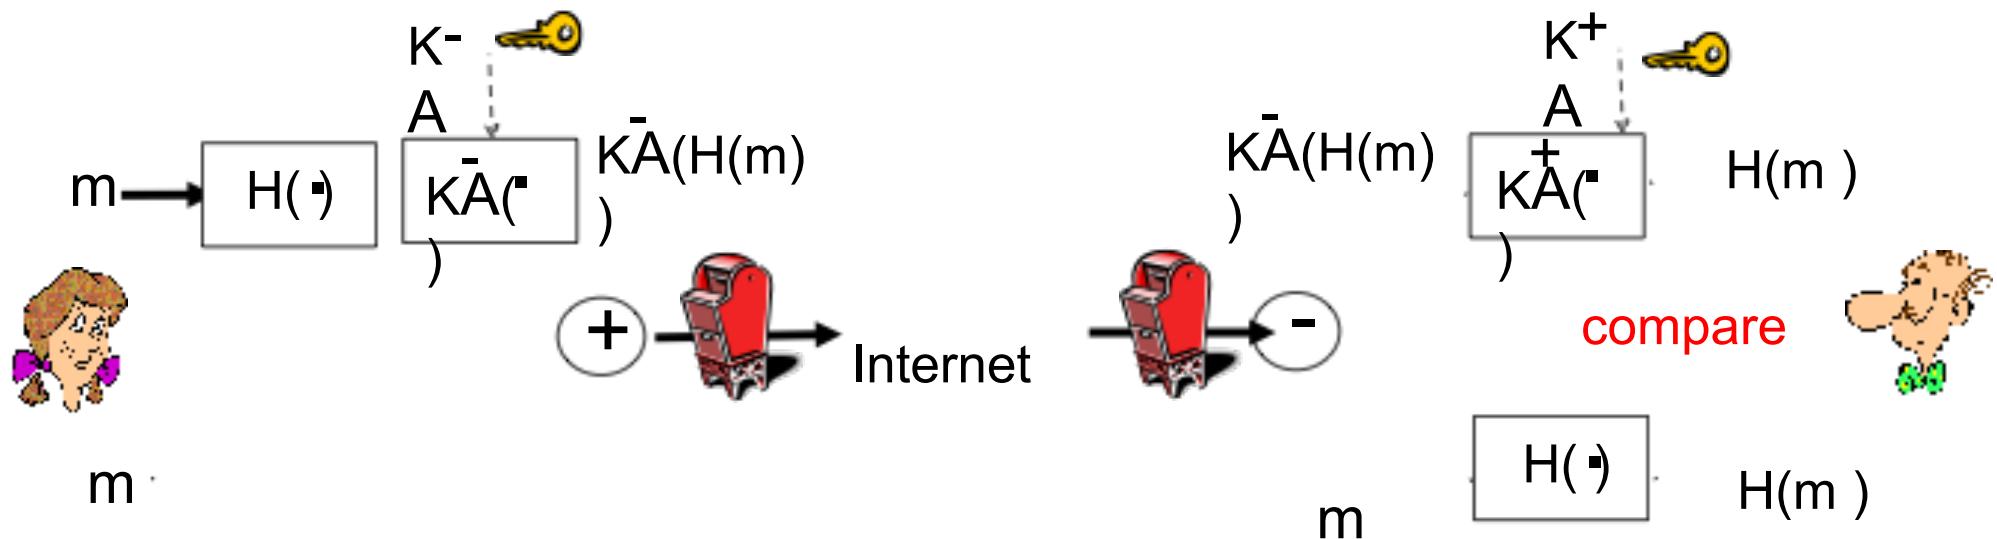

Bob:

- uses his private key to decrypt and recover KS
- uses KS to decrypt $KS(m)$ to recover m

Secure e-mail (continued)

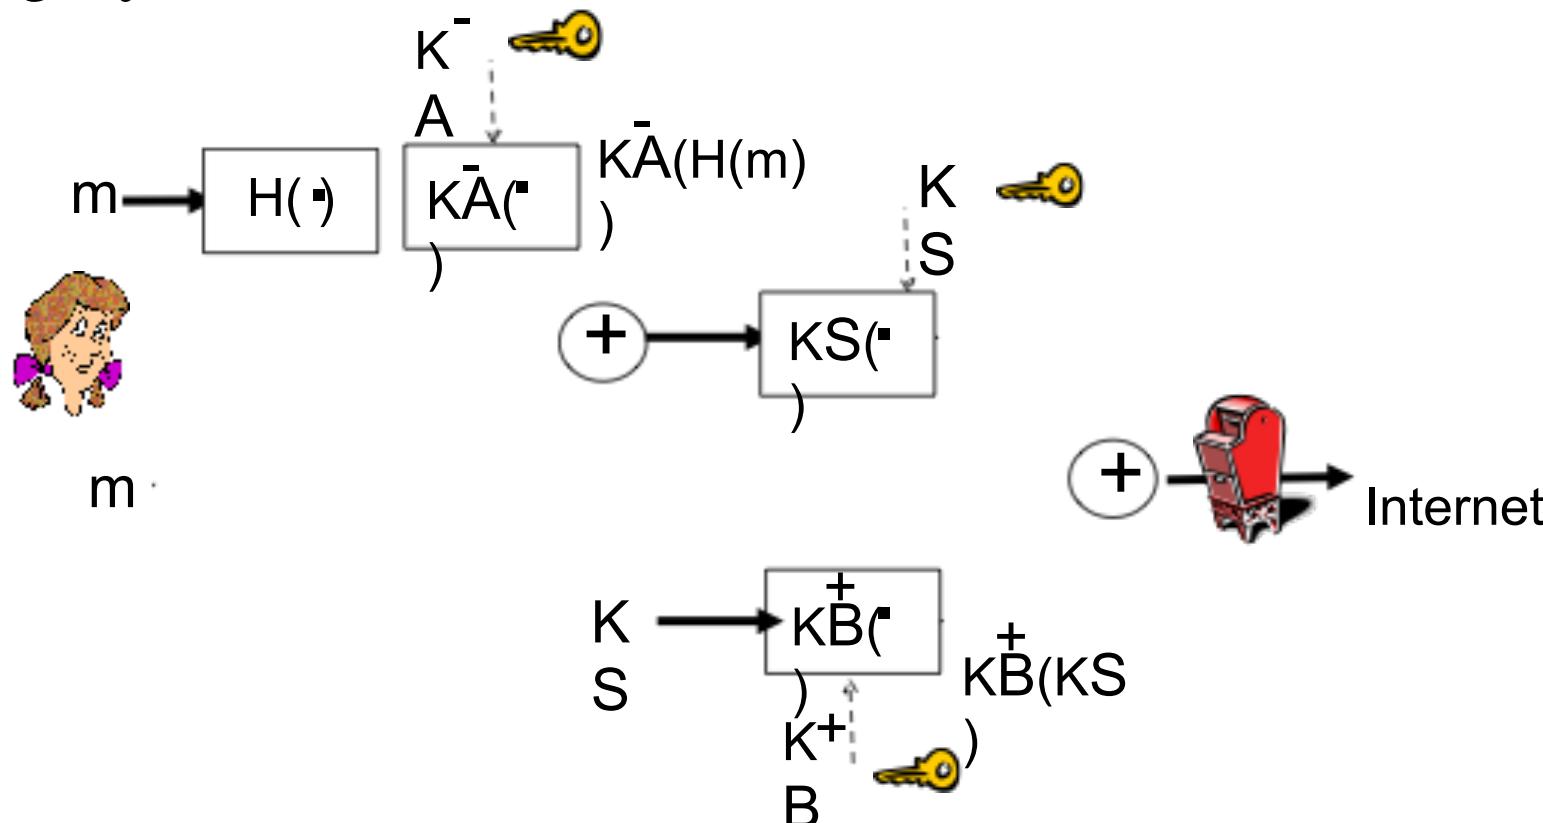

Alice wants to provide sender authentication message integrity

- Alice digitally signs message
- sends both message (in the clear) and digital signature

Secure e-mail (continued)

Alice wants to provide secrecy, sender authentication, message integrity.

Alice uses three keys: her private key, Bob's public key, newly created symmetric key

Chapter 8 roadmap

8.1 What is network security?

8.2 Principles of cryptography

8.3 Message integrity

8.4 Securing e-mail

8.5 Securing TCP connections: SSL

8.6 Network layer security: IPsec

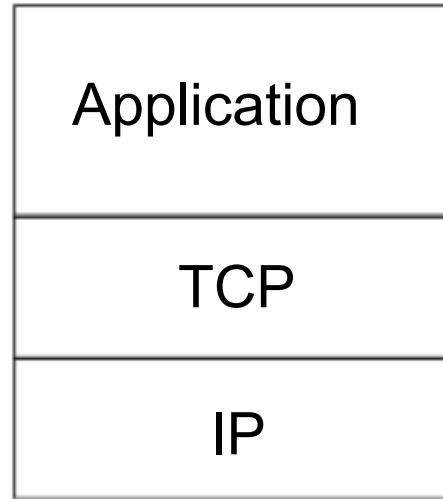

8.7 Securing wireless LANs

8.8 Operational security: firewalls and IDS

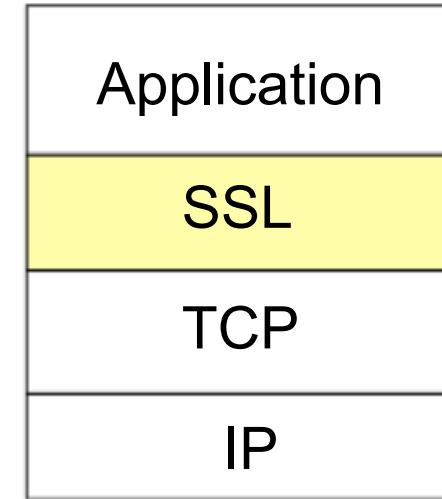

SSL: Secure Sockets Layer

- widely deployed security protocol
- supported by almost all browsers, web servers
- https
- billions \$/year over SSL
- mechanisms: [Woo 1994], implementation: Netscape
- variation -TLS: transport layer security, RFC 2246
- provides
 - *confidentiality*
 - *integrity*
 - *authentication*
- original goals:
 - Web e-commerce transactions
 - encryption (especially credit-card numbers)
 - Web-server authentication
 - optional client authentication
 - minimum hassle in doing business with new merchant
- available to all TCP applications
- secure socket interface

SSL and TCP/IP

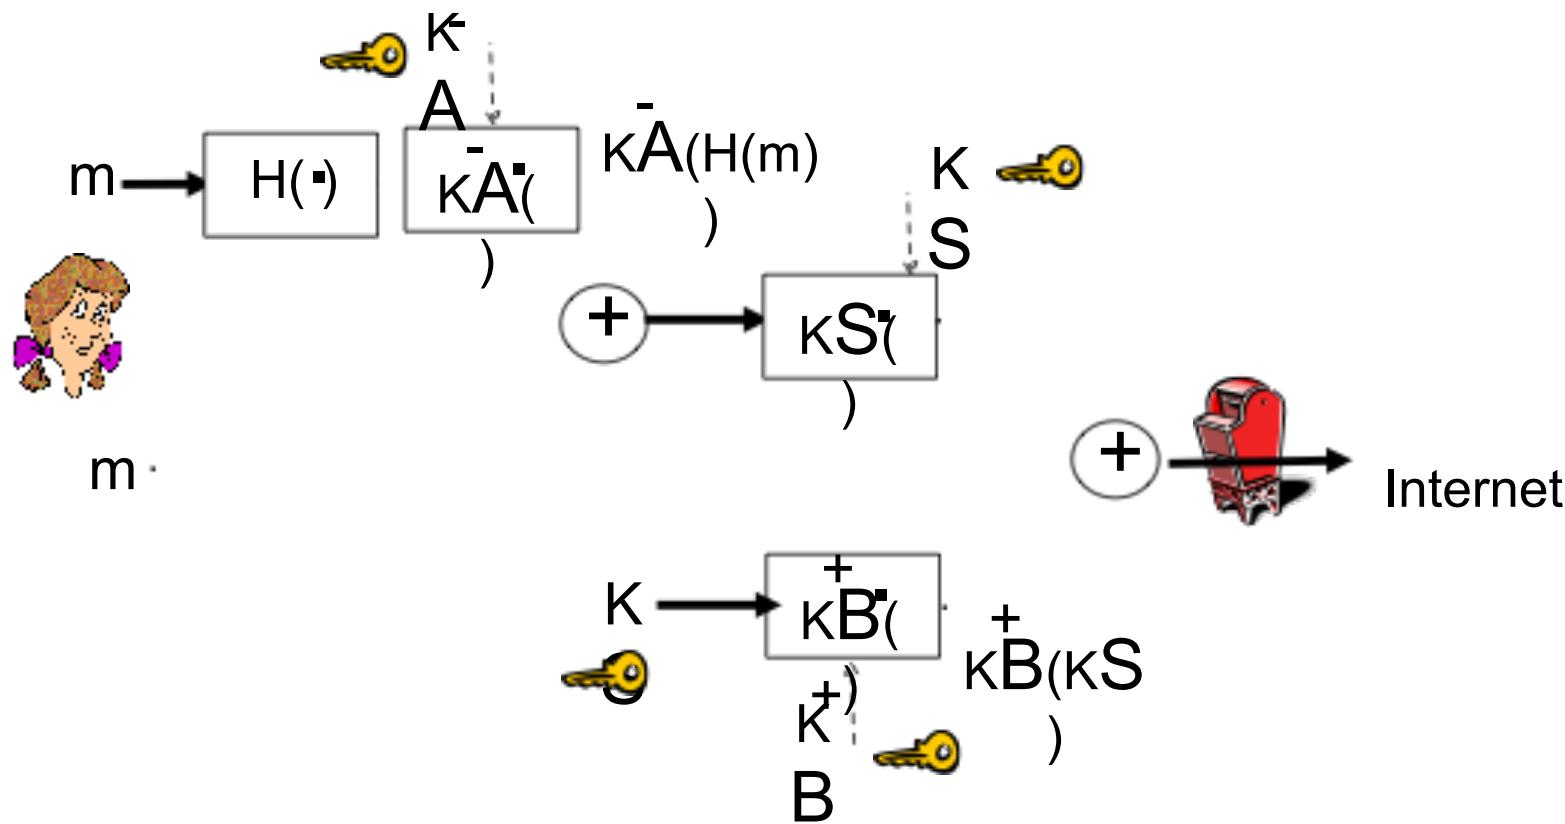

normal application

application with SSL

- SSL provides application programming interface (API) to applications
- C and Java SSL libraries/classes readily available

Could do something like PGP:

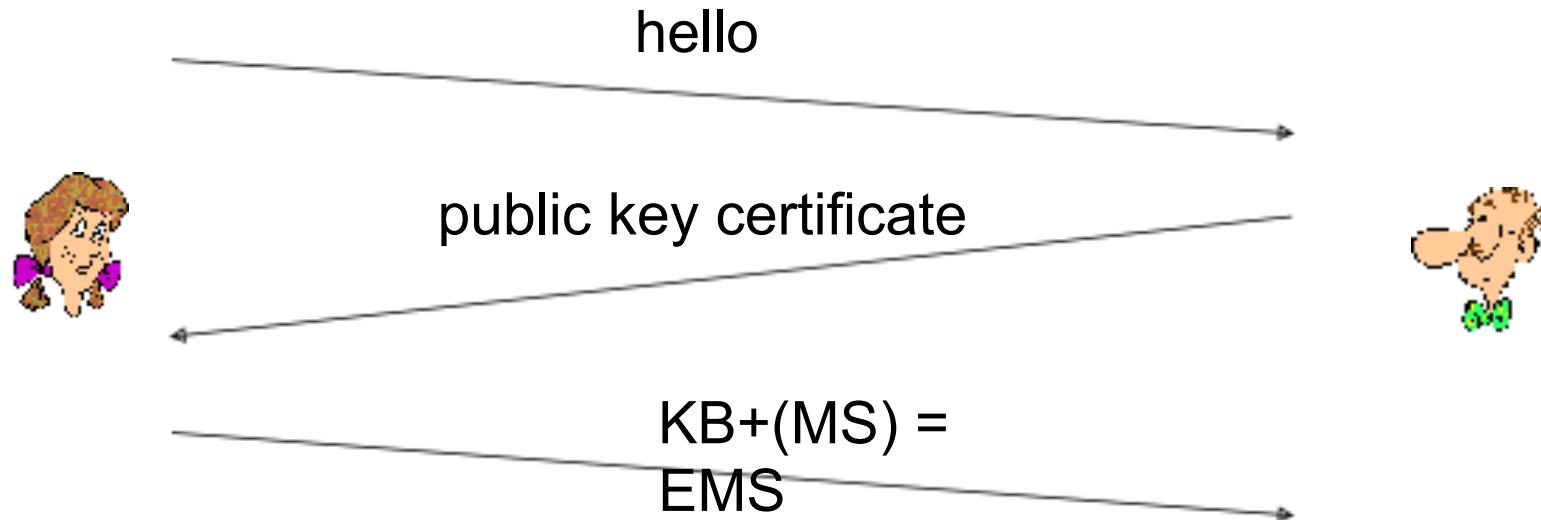

- but want to send byte streams & interactive data
- want set of secret keys for entire connection
- want certificate exchange as part of protocol: handshake phase

Toy SSL: a simple secure channel

- *handshake*: Alice and Bob use their certificates, private keys to authenticate each other and exchange shared secret
- *key derivation*: Alice and Bob use shared secret to derive set of keys
- *data transfer*: data to be transferred is broken up into series of records
- *connection closure*: special messages to securely close connection

Toy: a simple handshake

MS: master secret

EMS: encrypted master secret

Toy: key derivation

- considered bad to use same key for more than one cryptographic operation
 - use different keys for message authentication code (MAC) and encryption
- four keys:
 - K_c = encryption key for data sent from client to server
 - M_c = MAC key for data sent from client to server
 - K_s = encryption key for data sent from server to client
 - M_s = MAC key for data sent from server to client
- keys derived from key derivation function (KDF)
 - takes master secret and (possibly) some additional random data and creates the keys

Toy: data records

- why not encrypt data in constant stream as we write it to TCP?
 - where would we put the MAC? If at end, no message integrity until all data processed.
 - e.g., with instant messaging, how can we do integrity check over all bytes sent before displaying?
- instead, break stream in series of records
 - each record carries a MAC
 - receiver can act on each record as it arrives
- issue: in record, receiver needs to distinguish MAC from data
 - want to use variable-length records

Toy: sequence numbers

- *problem*: attacker can capture and replay record or re-order records
- *solution*: put sequence number into MAC:
 - $\text{MAC} = \text{MAC}(\text{M}_x, \text{sequence}\text{cell}\text{data})$
 - note: no sequence number field
- *problem*: attacker could replay all records
- *solution*: use nonce

TCP 上有，但 SSL 上沒有
attacker 可以換時間順序

sequence number 也必需被 encrypt 起來，而不是 plaintext

Toy: control information

- *problem:* truncation attack:
 - attacker forges TCP connection close segment
 - one or both sides thinks there is less data than there actually is.
- *solution:* record types, with one type for closure
 - type 0 for data; type 1 for closure
- $\text{MAC} = \text{MAC}(\text{M}_x, \text{sequence}\|\text{type}\|\text{data})$

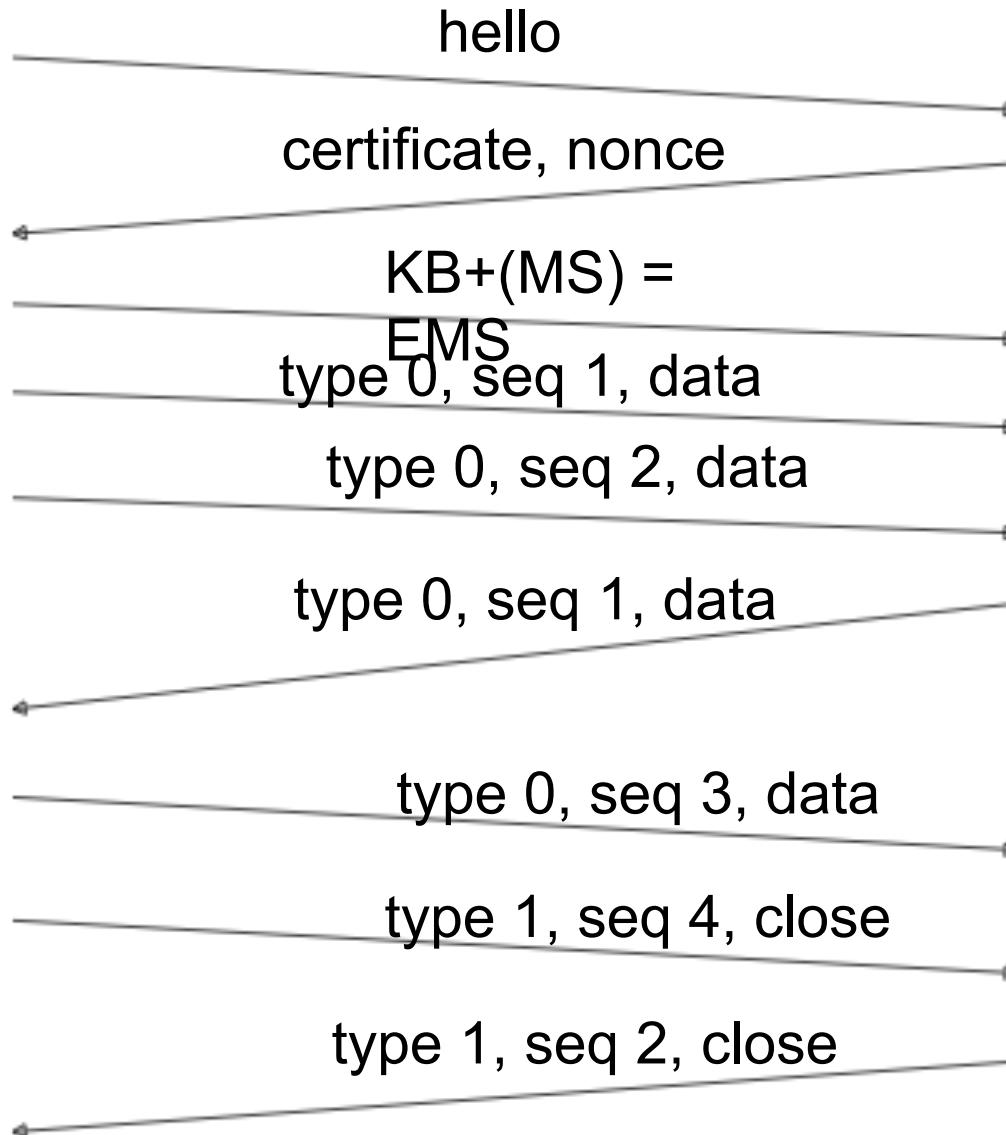

Toy SSL: summary

不會考

e

pt
e
d

bob.com

Toy SSL isn't complete

- how long are fields?
- which encryption protocols?
- want negotiation?
 - allow client and server to support different encryption algorithms
 - allow client and server to choose together specific algorithm before data transfer

SSL cipher suite

- cipher suite
 - public-key algorithm
 - symmetric encryption algorithm
 - MAC algorithm
- SSL supports several cipher suites
- negotiation: client, server agree on cipher suite
 - client offers choice
 - server picks one

common SSL symmetric ciphers

DES – Data Encryption Standard: block

3DES – Triple strength: block

RC2 – Rivest Cipher 2: block

RC4 – Rivest Cipher 4: stream

SSL Public key encryption RSA

Real SSL: handshake (1)

Purpose

1. server authentication
2. negotiation: agree on crypto algorithms
3. establish keys
4. client authentication (optional)

Real SSL: handshake (2)

1. client sends list of algorithms it supports, along with client nonce
2. server chooses algorithms from list; sends back: choice + certificate + server nonce
3. client verifies certificate, extracts server's public key, generates pre_master_secret, encrypts with server's public key, sends to server
4. client and server independently compute encryption and MAC keys from pre_master_secret and nonces
5. client sends a MAC of all the handshake messages
6. server sends a MAC of all the handshake messages

Real SSL: handshaking (3)

last 2 steps protect handshake from tampering

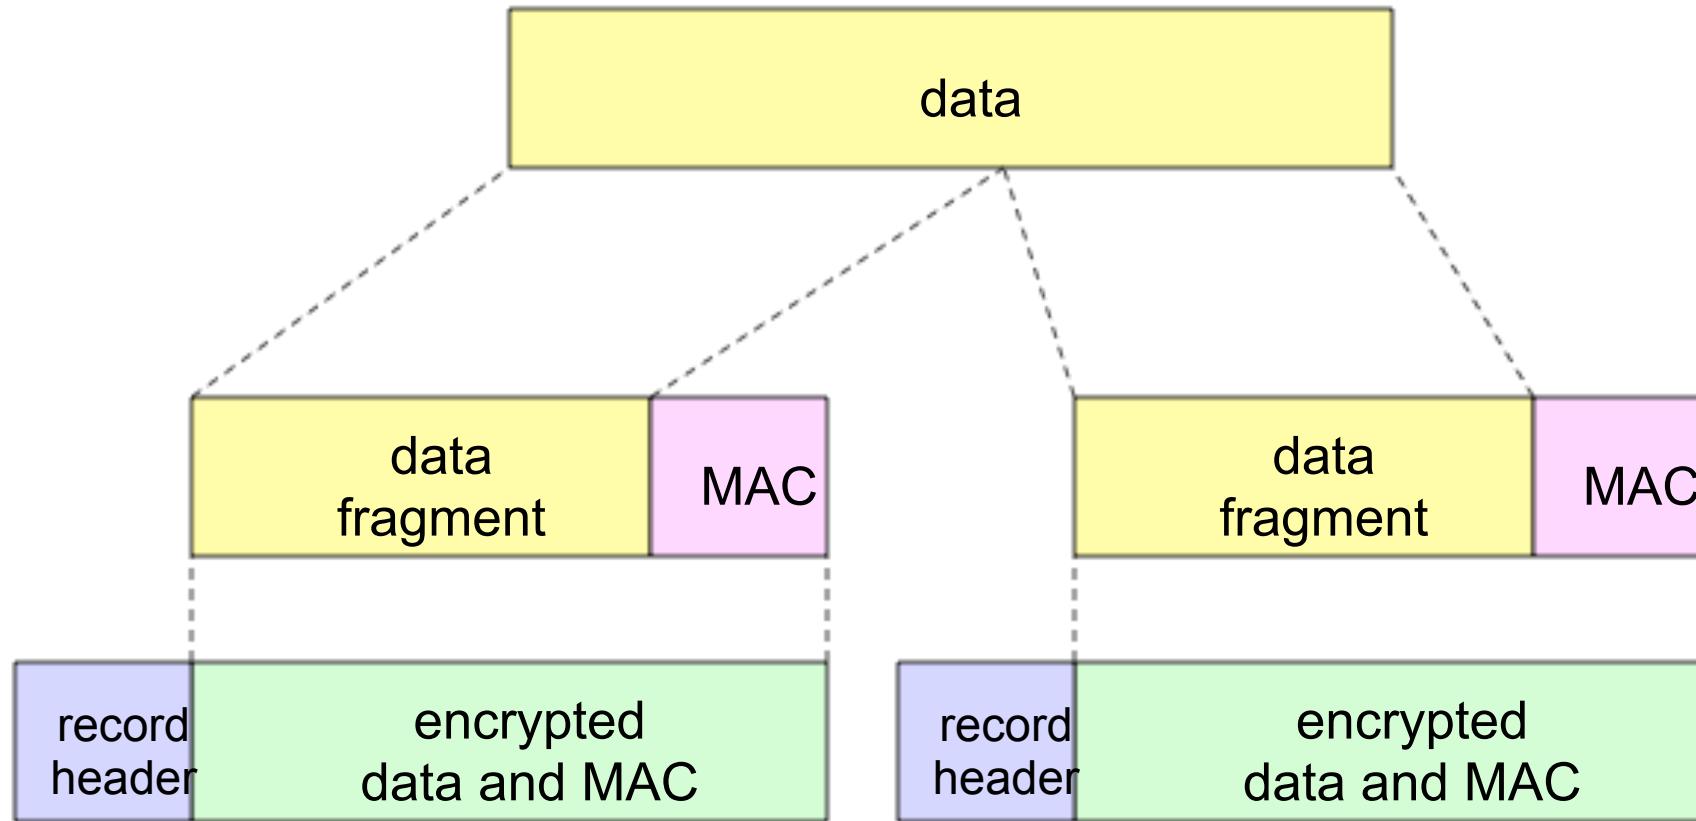

- client typically offers range of algorithms, some strong, some weak
- man-in-the middle could delete stronger algorithms from list
- last 2 steps prevent this
 - last two messages are encrypted

Real SSL: handshaking (4)

- why two random nonces?
- suppose Trudy sniffs all messages between Alice & Bob
- next day, Trudy sets up TCP connection with Bob, sends exact same sequence of records
 - Bob (Amazon) thinks Alice made two separate orders for the same thing
 - solution: Bob sends different random nonce for each connection. This causes encryption keys to be different on the two days
 - Trudy's messages will fail Bob's integrity check

SSL record protocol

跳過

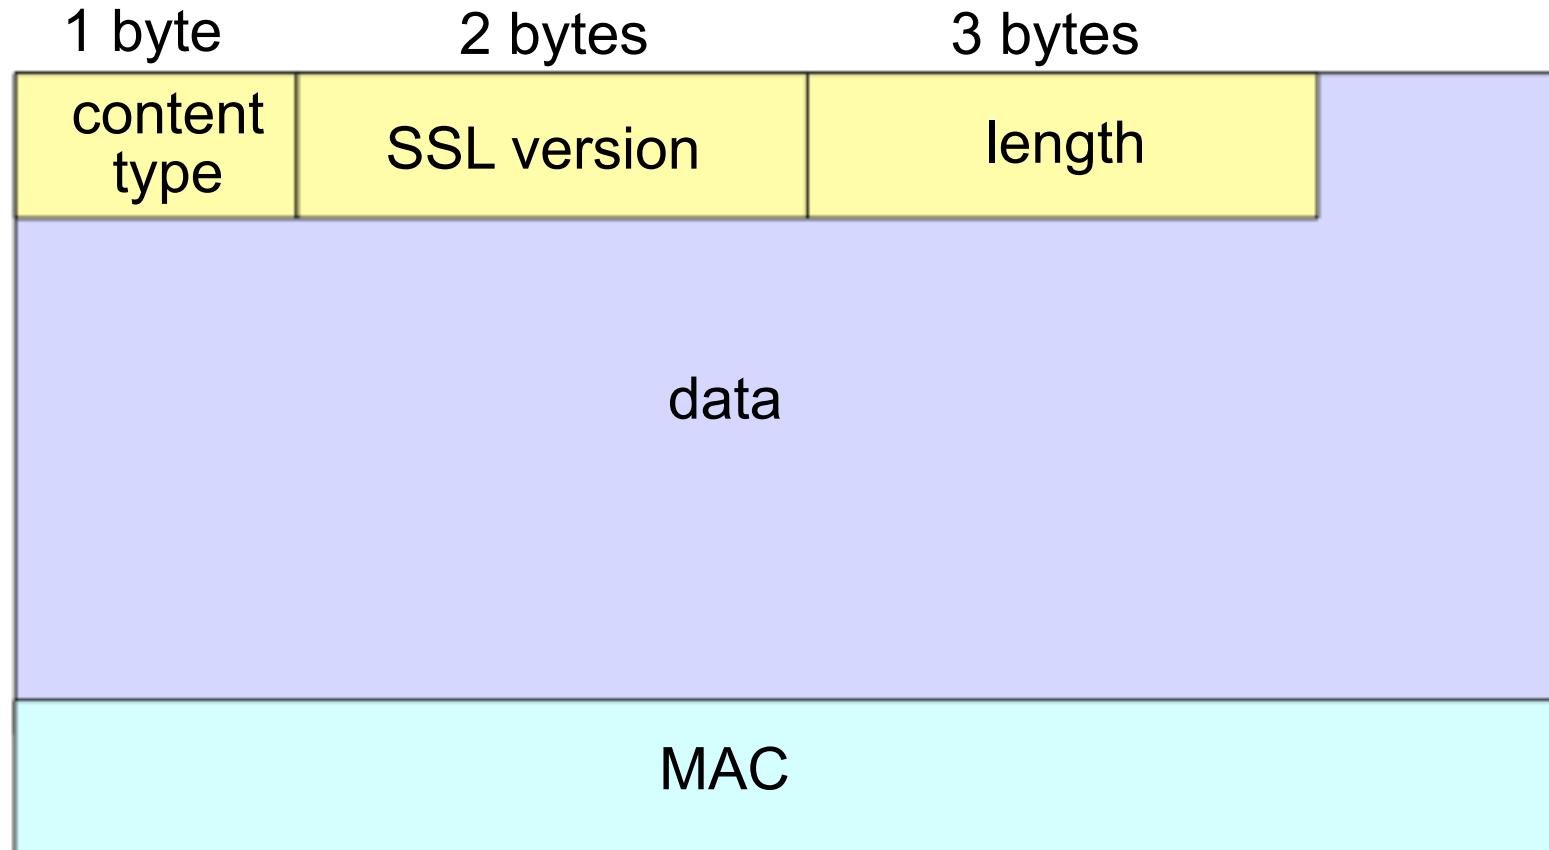

record header: content type; version; length

MAC: includes sequence number, MAC key

fragment^{M_x}: each SSL fragment 214 bytes (~16 Kbytes)

SSL record format

跳過

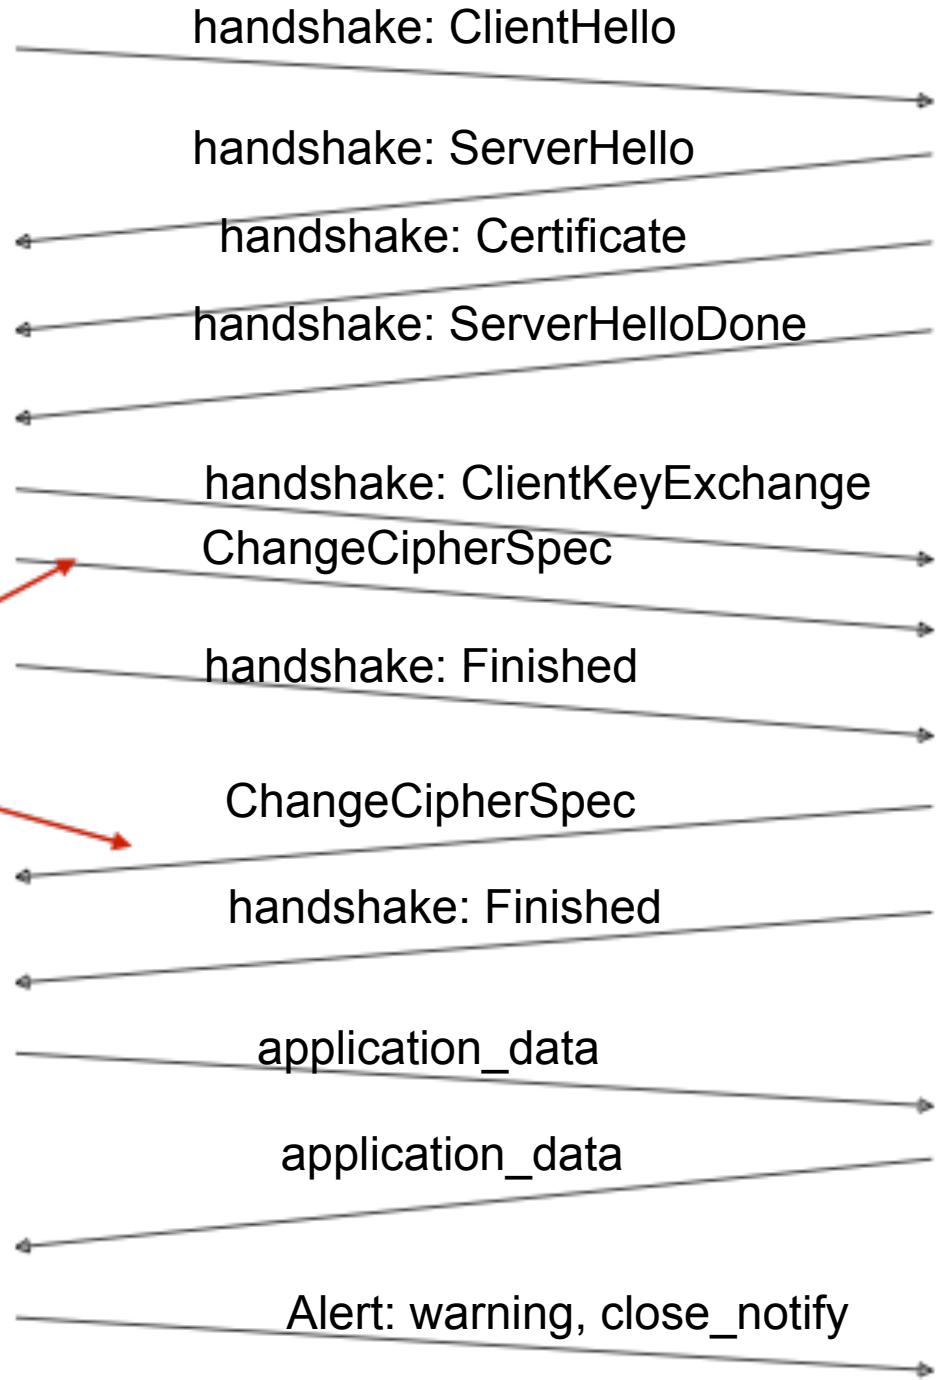

data and MAC encrypted (symmetric algorithm)

Real SSL connection

*everything
henceforth
is encrypted*

TCP FIN
follows

Key derivation

- client nonce, server nonce, and pre-master secret input into pseudo random-number generator.
 - produces master secret
- master secret and new nonces input into another random-number generator: “key block”
 - because of resumption: TBD
- key block sliced and diced:
 - client MAC key
 - server MAC key
 - client encryption key
 - server encryption key
 - client initialization vector (IV)
 - server initialization vector (IV)

Chapter 8 roadmap

- 8.1 What is network security?
- 8.2 Principles of cryptography
- 8.3 Message integrity
- 8.4 Securing e-mail
- 8.5 Securing TCP connections: SSL
- 8.6 Network layer security: IPsec*
- 8.7 Securing wireless LANs
- 8.8 Operational security: firewalls and IDS

What is network-layer confidentiality ?

between two network entities:

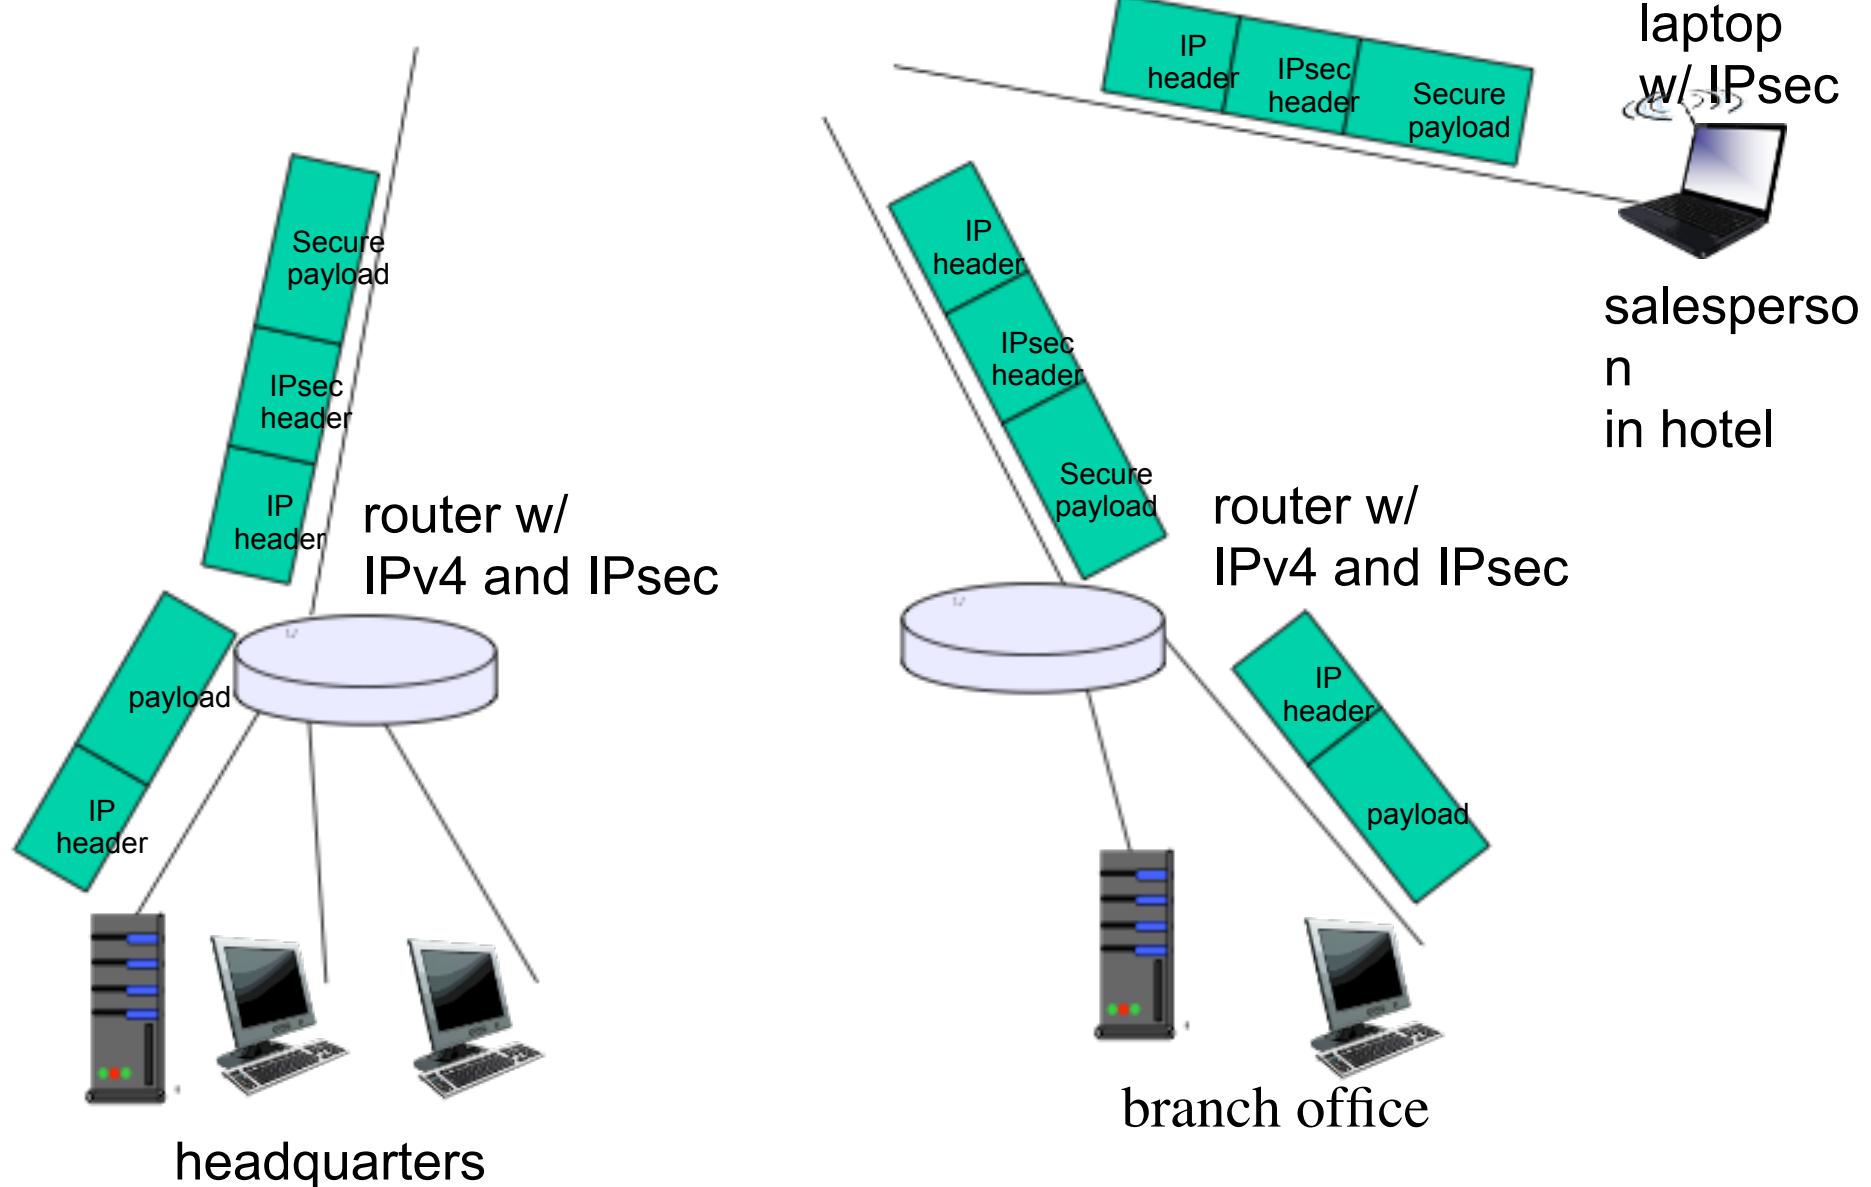

- sending entity encrypts datagram payload, payload could be:
 - TCP or UDP segment, ICMP message, OSPF message
- all data sent from one entity to other would be hidden:
 - web pages, e-mail, P2P file transfers, TCP SYN packets
 - ...
- “blanket coverage”

Virtual Private Networks (VPNs)

motivation:

- institutions often want private networks for security.
 - costly: separate routers, links, DNS infrastructure.
- VPN: institution's inter-office traffic is sent over public Internet instead
 - encrypted before entering public Internet
 - logically separate from other traffic

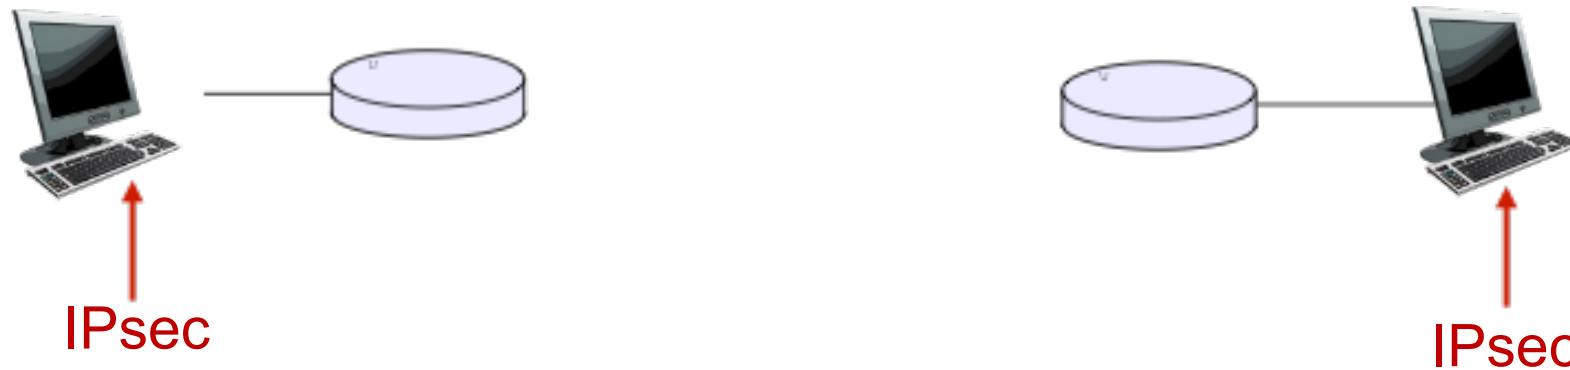

Virtual Private Networks (VPNs)

IPsec services

- data integrity
- origin authentication
- replay attack prevention
- confidentiality
- two protocols providing different service models:
 - AH
 - ESP

IPsec transport mode

- IPsec datagram emitted and received by end-system
- protects upper level protocols

IPsec – tunneling mode

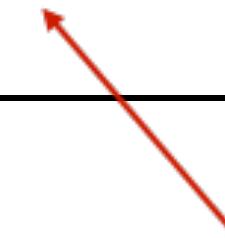

- edge routers IPsec-aware
- hosts IPsec-aware

Two IPsec protocols

- Authentication Header (AH) protocol
 - provides source authentication & data integrity but *not* confidentiality
- Encapsulation Security Protocol (ESP)
 - provides source authentication, data integrity, *and* confidentiality
 - more widely used than AH

Four combinations are possible!

Host mode with AH	Host mode with ESP
Tunnel mode with AH	Tunnel mode with ESP

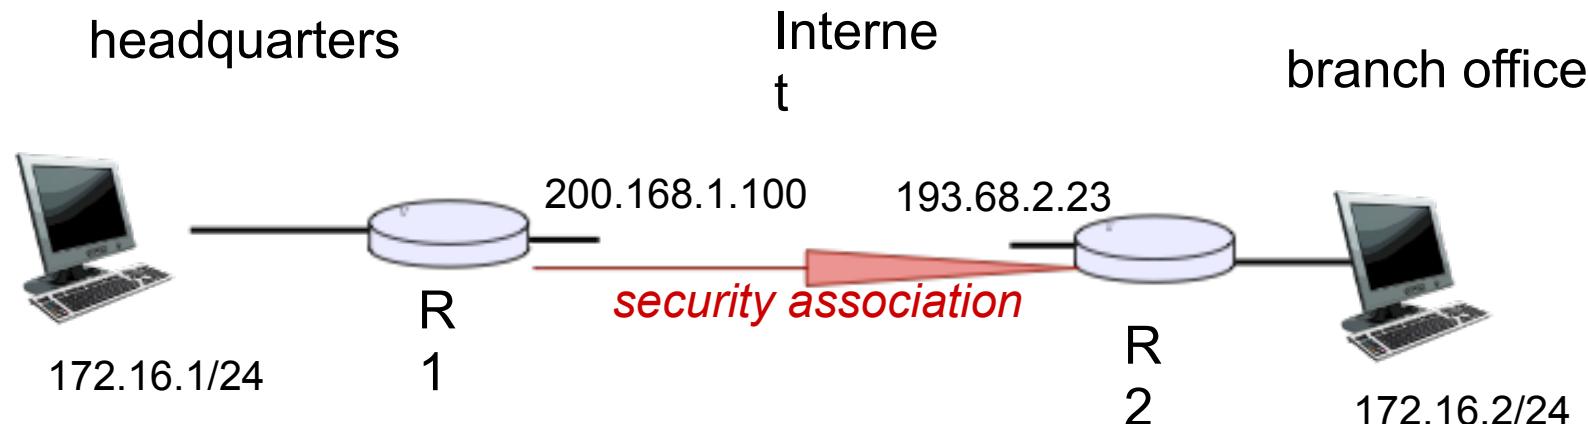

most common and
most important

Security associations (SAs)

- before sending data, “**security association (SA)**” established from sending to receiving entity
 - SAs are simplex: for only one direction
- ending, receiving entities maintain *state information* about SA
 - recall: TCP endpoints also maintain state info
 - IP is connectionless; IPsec is connection-oriented!
- how many SAs in VPN w/ headquarters, branch office, and n traveling salespeople?

Example SA from R1 to R2

R1 stores for SA:

- 32-bit SA identifier: *Security Parameter Index (SPI)*
- origin SA interface (200.168.1.100)
- destination SA interface (193.68.2.23)
- type of encryption used (e.g., 3DES with CBC)
- encryption key
- type of integrity check used (e.g., HMAC with MD5)
- authentication key

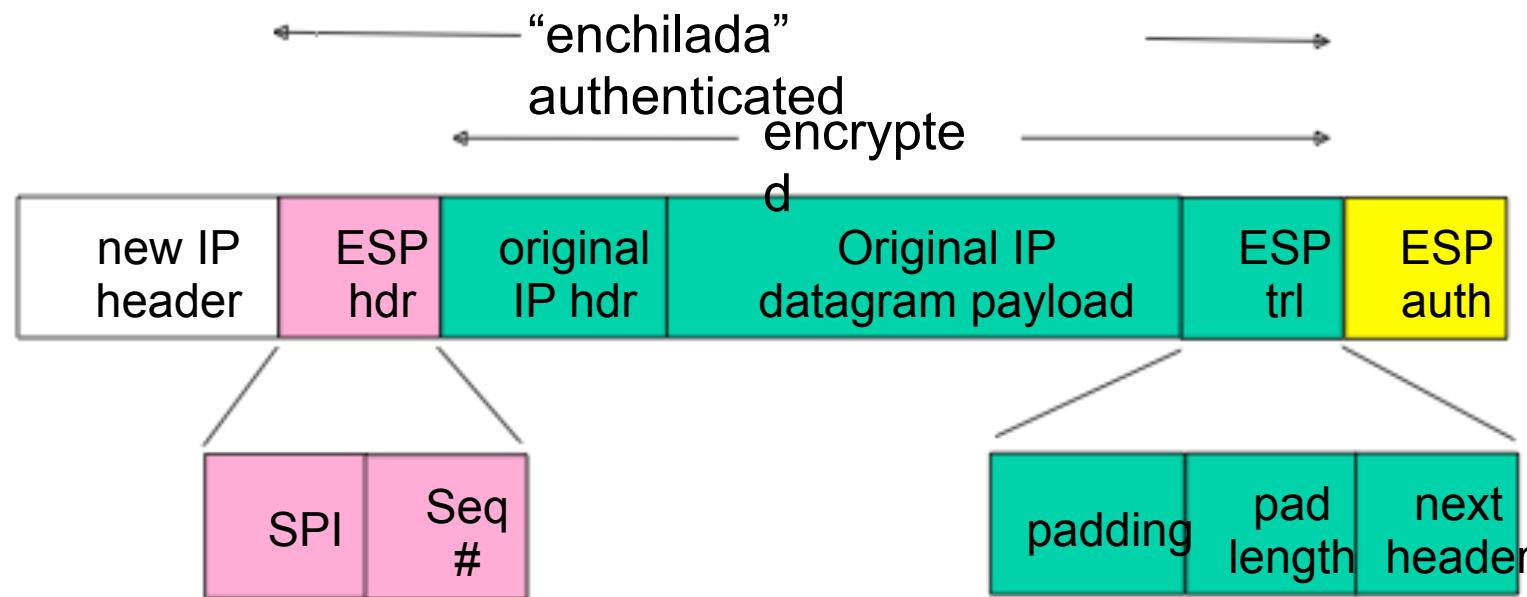

Security Association Database (SAD)

- endpoint holds SA state in *security association database (SAD)*, where it can locate them during processing.
- with n salespersons, $2 + 2n$ SAs in R1's SAD
- when sending IPsec datagram, R1 accesses SAD to determine how to process datagram.
- when IPsec datagram arrives to R2, R2 examines SPI in IPsec datagram, indexes SAD with SPI, and processes datagram accordingly.

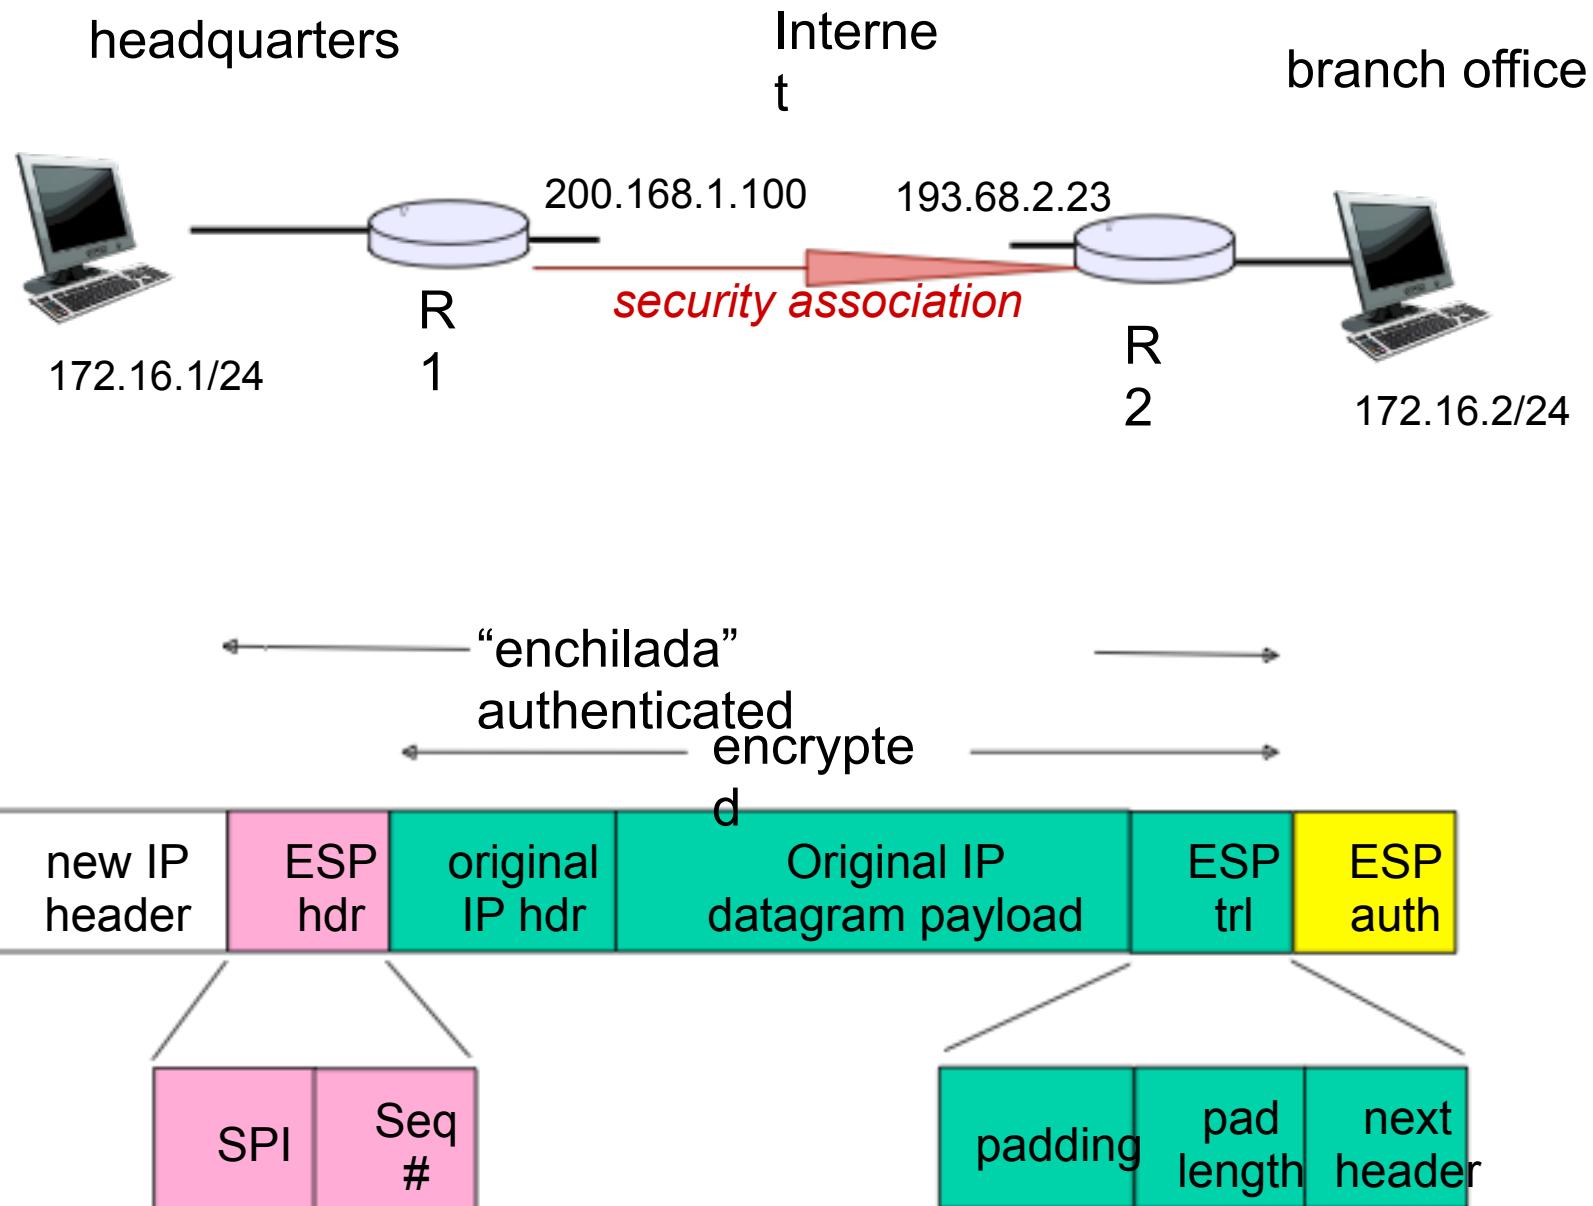

IPsec datagram

跳過

focus for now on tunnel mode with ESP

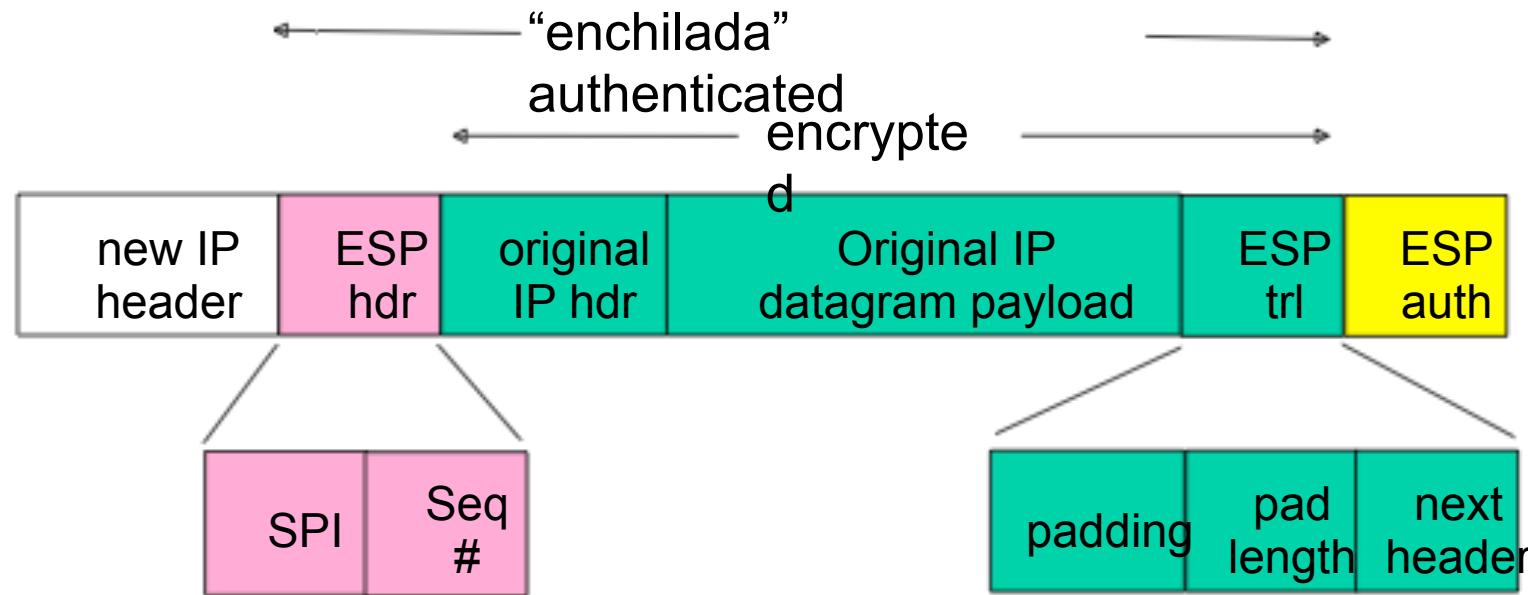

What happens?

R1: convert original datagram to IPsec datagram

- appends to back of original datagram (which includes original header fields!) an “ESP trailer” field.
- encrypts result using algorithm & key specified by SA.
- appends to front of this encrypted quantity the “ESP header, creating “enchilada”.
- creates authentication MAC over the *whole enchilada*, using algorithm and key specified in SA;
- appends MAC to back of *enchilada*, forming *payload*;
- creates brand new IP header, with all the classic IPv4 header fields, which it appends before payload

Inside the enchilada:

- ESP trailer: Padding for block ciphers
- ESP header:
 - SPI, so receiving entity knows what to do
 - Sequence number, to thwart replay attacks
- MAC in ESP auth field is created with shared secret key

IPsec sequence numbers

- for new SA, sender initializes seq. # to 0
- each time datagram is sent on SA:
 - sender increments seq # counter
 - places value in seq # field
- goal:
 - prevent attacker from sniffing and replaying a packet
 - receipt of duplicate, authenticated IP packets may disrupt service
- method:
 - destination checks for duplicates
 - doesn't keep track of *all* received packets; instead uses a window

Security Policy Database (SPD)

- policy: For a given datagram, sending entity needs to know if it should use IPsec
- needs also to know which SA to use
 - may use: source and destination IP address; protocol number
- info in SPD indicates “what” to do with arriving datagram
- info in SAD indicates “how” to do it

Summary: IPsec services

- suppose Trudy sits somewhere between R1 and R2. she doesn't know the keys.
 - will Trudy be able to see original contents of datagram? How about source, dest IP address, transport protocol, application port?
 - flip bits without detection?
 - masquerade as R1 using R1's IP address?
 - replay a datagram?

IKE: Internet Key Exchange

- *previous examples:* manual establishment of IPsec SAs in IPsec endpoints:
Example SA
 SPI: 12345
 Source IP: 200.168.1.100
 Dest IP: 193.68.2.23
 Protocol: ESP
 Encryption algorithm: 3DES-cbc
 HMAC algorithm: MD5
 Encryption key: 0x7aeaca...
 HMAC key: 0xc0291f...
- manual keying is impractical for VPN with 100s of endpoints
- instead use *IPsec IKE (Internet Key Exchange)*

IKE: PSK and PKI

- authentication (prove who you are) with either
 - pre-shared secret (PSK) or
 - with PKI (public/private keys and certificates).
- PSK: both sides start with secret
 - run IKE to authenticate each other and to generate IPsec SAs (one in each direction), including encryption, authentication keys
- PKI: both sides start with public/private key pair, certificate
 - run IKE to authenticate each other, obtain IPsec SAs (one in each direction).
 - similar with handshake in SSL.

IKE phases

- IKE has two phases
 - *phase 1*: establish bi-directional IKE SA
 - note: IKE SA different from IPsec SA
 - aka ISAKMP security association
 - *phase 2*: ISAKMP is used to securely negotiate IPsec pair of SAs
- phase 1 has two modes: aggressive mode and main mode
 - aggressive mode uses fewer messages
 - main mode provides identity protection and is more flexible

IPsec summary

- IKE message exchange for algorithms, secret keys, SPI numbers
- either AH or ESP protocol (or both)
 - AH provides integrity, source authentication
 - ESP protocol (with AH) additionally provides encryption
- IPsec peers can be two end systems, two routers/firewalls, or a router/firewall and an end system

Chapter 8 roadmap

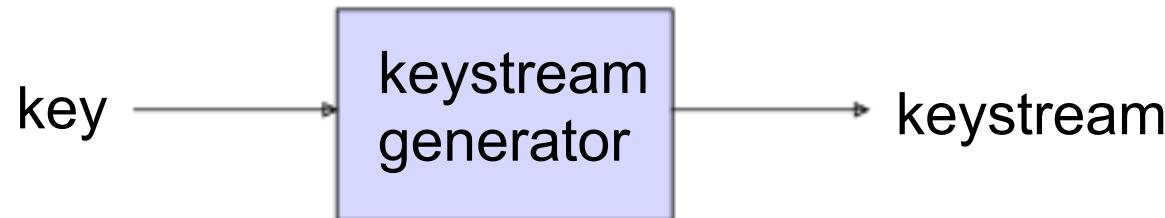

- 8.1 What is network security?
- 8.2 Principles of cryptography
- 8.3 Message integrity
- 8.4 Securing e-mail
- 8.5 Securing TCP connections: SSL
- 8.6 Network layer security: IPsec
- 8.7 Securing wireless LANs*
- 8.8 Operational security: firewalls and IDS

WEP design goals

- symmetric key crypto
 - confidentiality
 - end host authorization
 - data integrity
- self-synchronizing: each packet separately encrypted
 - given encrypted packet and key, can decrypt; can continue to decrypt packets when preceding packet was lost (unlike Cipher Block Chaining (CBC) in block ciphers)
- Efficient
 - implementable in hardware or software

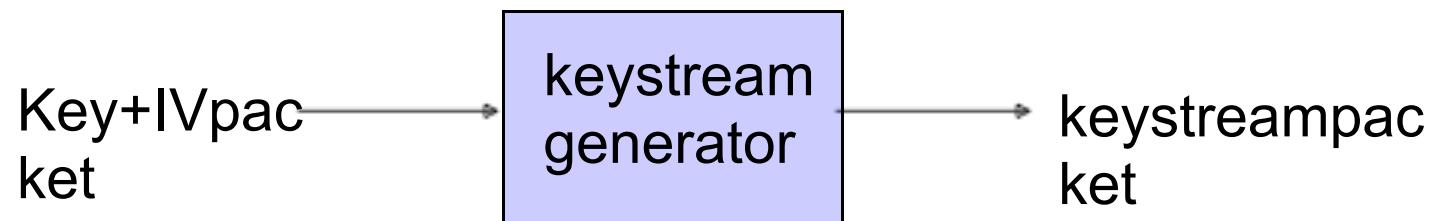

Review: symmetric stream ciphers

- *combine each byte of keystream with byte of plaintext to get ciphertext:*
 - $m(i)$ = ith unit of message
 - $ks(i)$ = ith unit of keystream
 - $c(i)$ = ith unit of ciphertext
 - $c(i) = ks(i) \square m(i)$ (\square = exclusive or)
 - $m(i) = ks(i) \square c(i)$
- WEP uses RC4

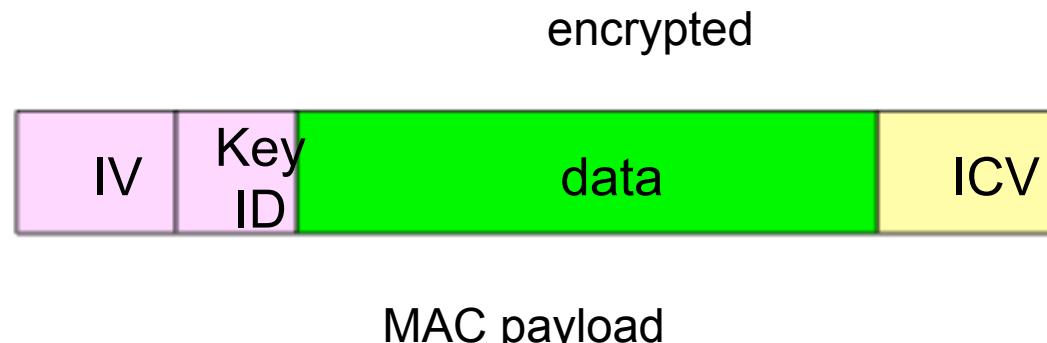

Stream cipher and packet independence

- recall design goal: each packet separately encrypted
- if for frame $n+1$, use keystream from where we left off for frame n , then each frame is not separately encrypted
 - need to know where we left off for packet n
- WEP approach: initialize keystream with key + new IV for each packet:

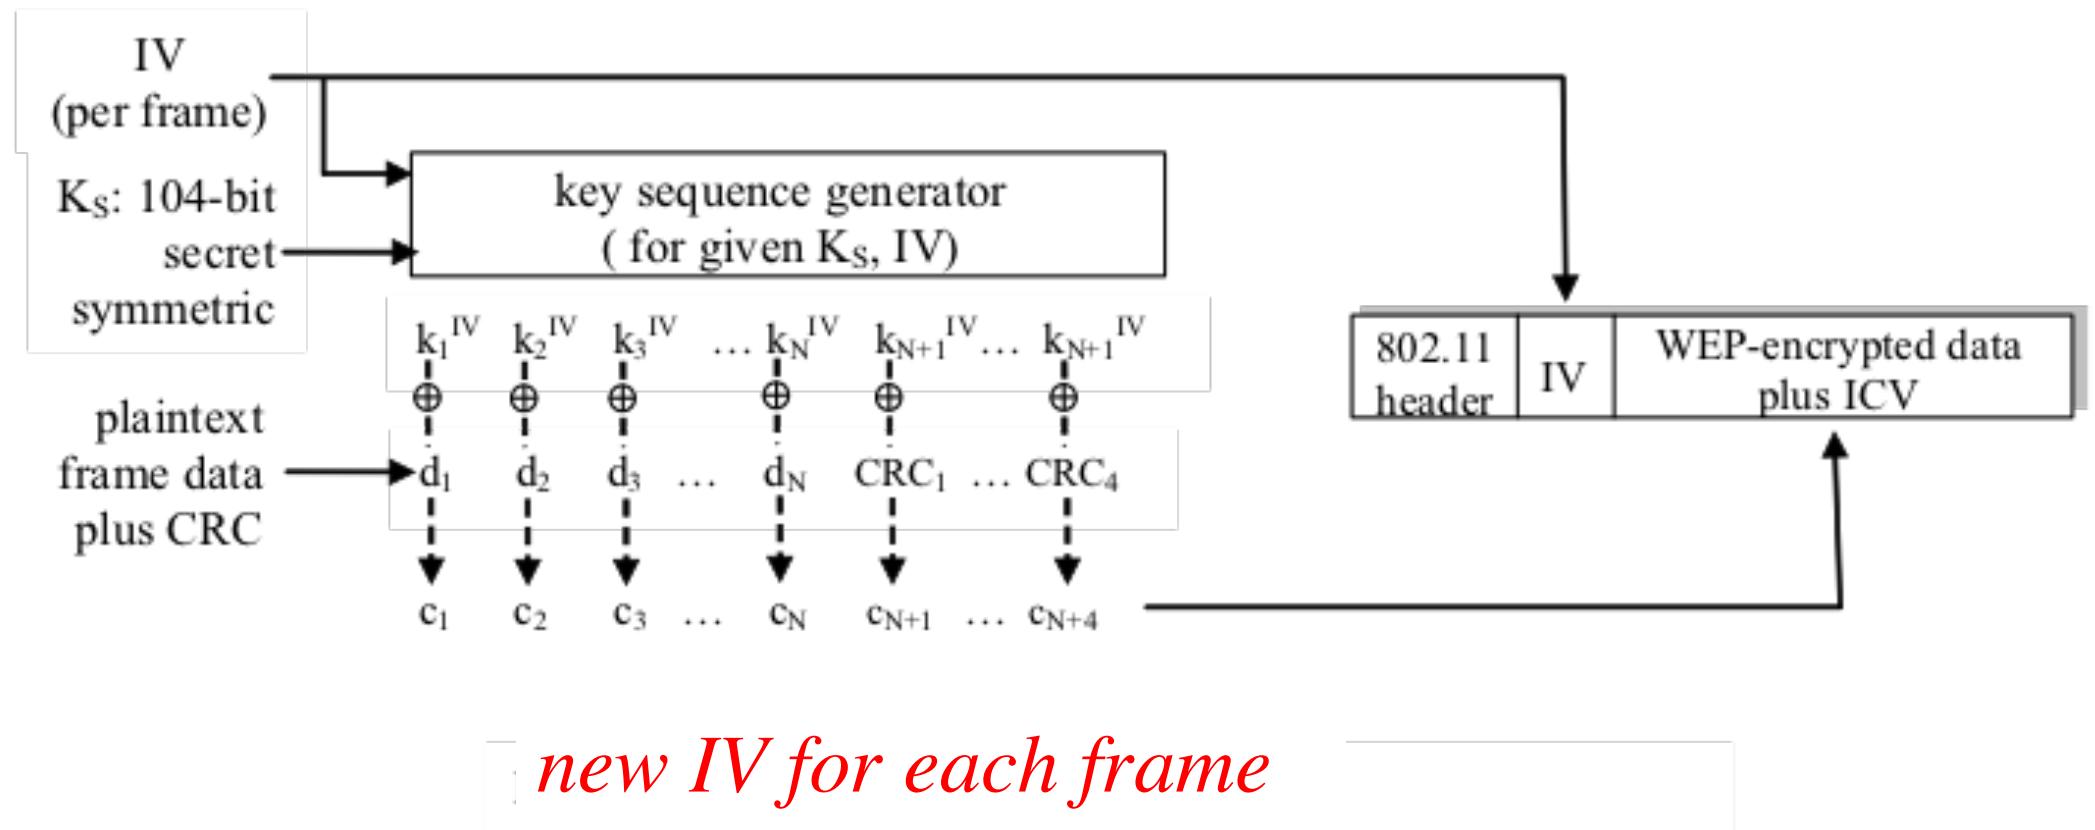

WEP encryption (1)

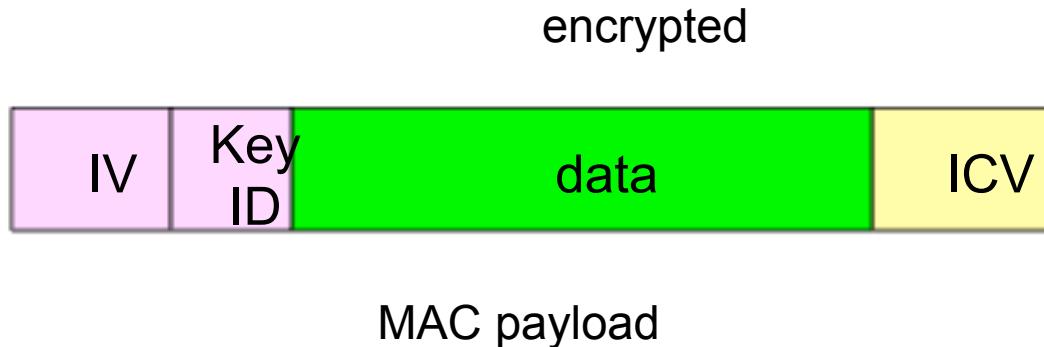

- sender calculates Integrity Check Value (ICV, four-byte hash/CRC over data)
- each side has 104-bit shared key
- sender creates 24-bit initialization vector (IV), appends to key: gives 128-bit key
- sender also appends keyID (in 8-bit field)
- 128-bit key inputted into pseudo random number generator to get keystream
- data in frame + ICV is encrypted with RC4:
 - bytes of keystream are XORed with bytes of data & ICV
 - IV & keyID are appended to encrypted data to create payload
 - payload inserted into 802.11 frame

WEP encryption (2)

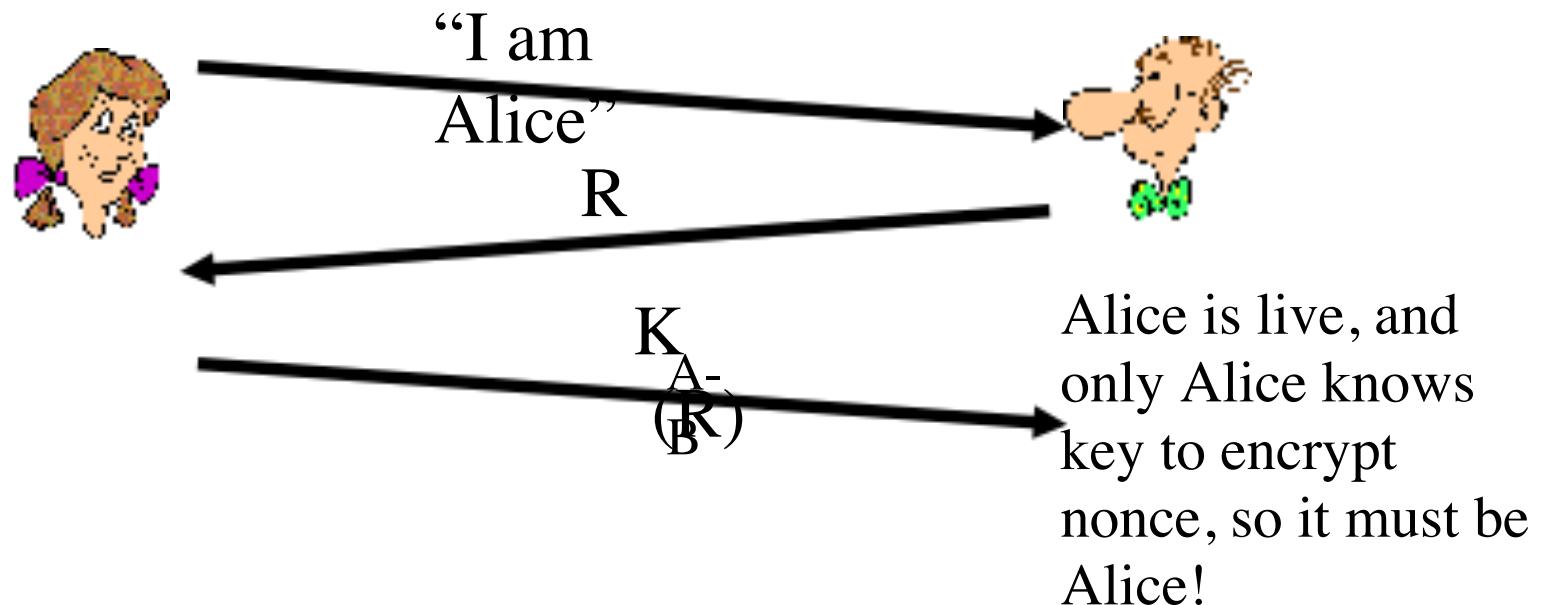

WEP decryption overview

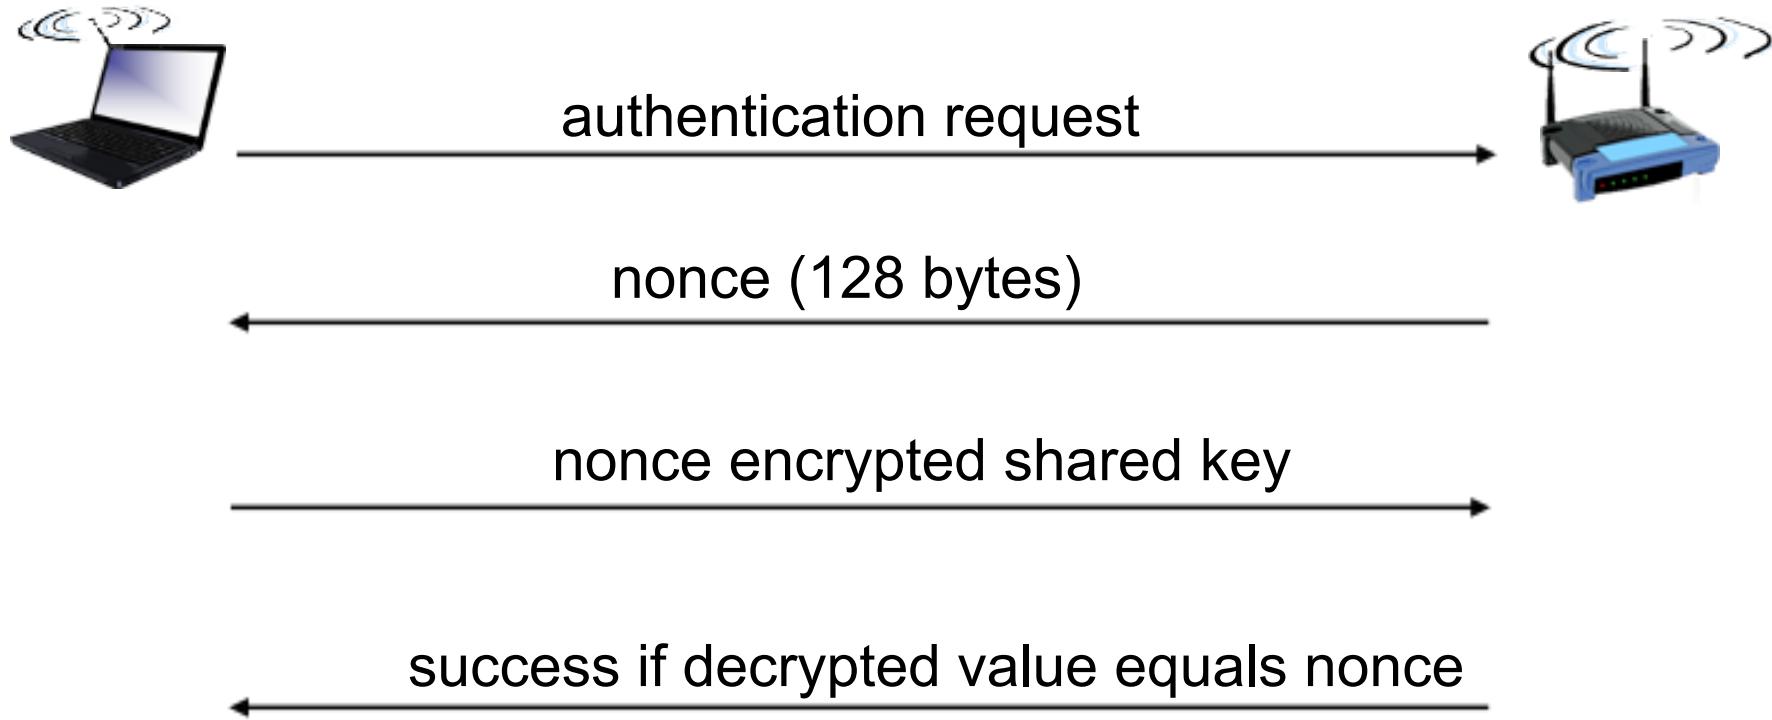

- receiver extracts IV
- inputs IV, shared secret key into pseudo random generator, gets keystream
- XORs keystream with encrypted data to decrypt data + ICV
- verifies integrity of data with ICV
 - note: message integrity approach used here is different from MAC (message authentication code) and signatures (using PKI).

End-point authentication w/ nonce

Nonce: number (R) used only *once –in-a-lifetime*
How to prove Alice “live”: Bob sends Alice *nonce*, R. Alice must return R, encrypted with shared secret key

WEP authentication

Notes:

- not all APs do it, even if WEP is being used
- AP indicates if authentication is necessary in beacon frame
- done before association

Breaking 802.11 WEP encryption

security hole:

- 24-bit IV, one IV per frame, -> IV's eventually reused
- IV transmitted in plaintext -> IV reuse detected

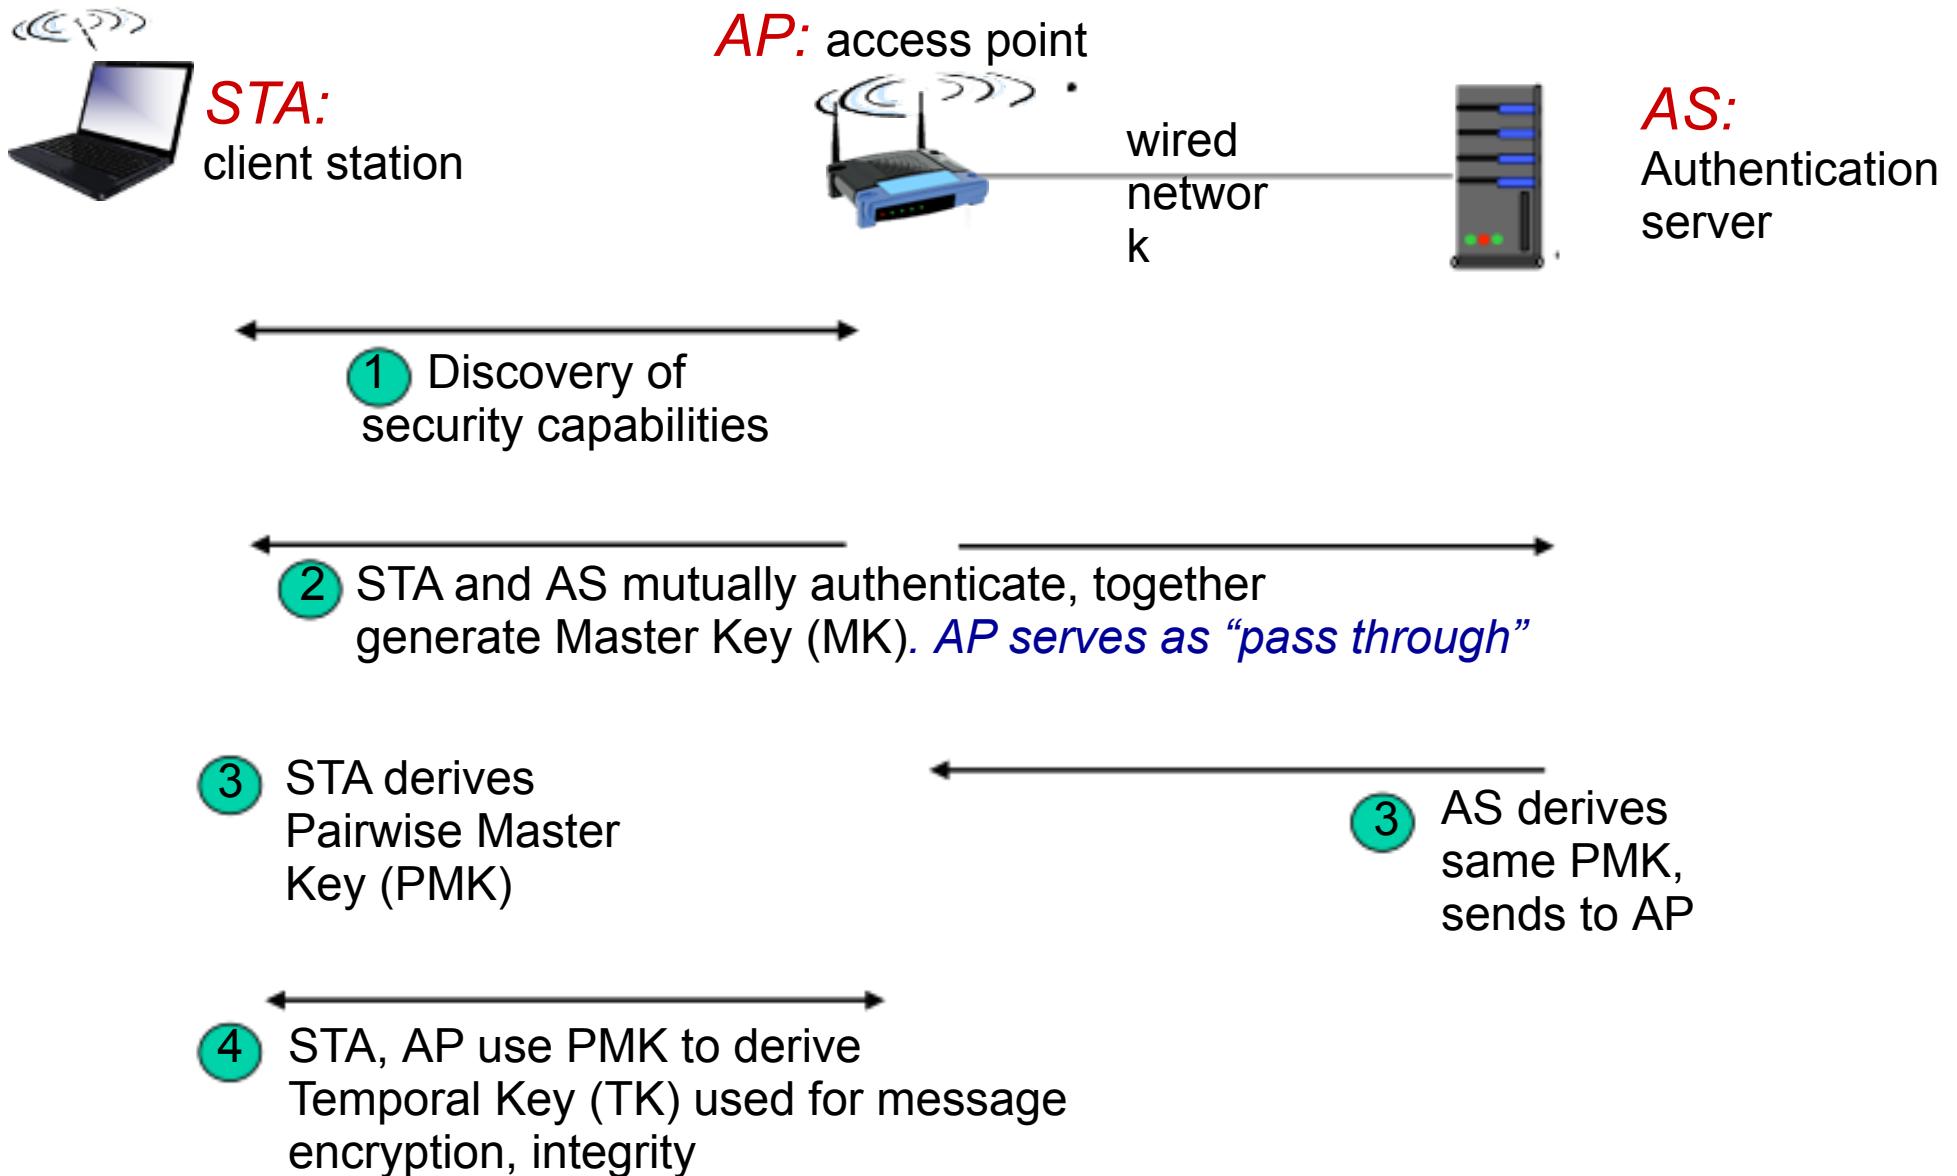

attack:

- Trudy causes Alice to encrypt known plaintext d1 d2 d3 d4
...
• Trudy sees: $c_i = d_i \text{ XOR } k_i \text{IV}$
• Trudy knows c_i d_i , so can compute $k_i \text{IV}$
• Trudy knows encrypting key sequence $k_1 \text{IV}$ $k_2 \text{IV}$ $k_3 \text{IV}$...
• Next time IV is used, Trudy can decrypt!

802.11i: improved security

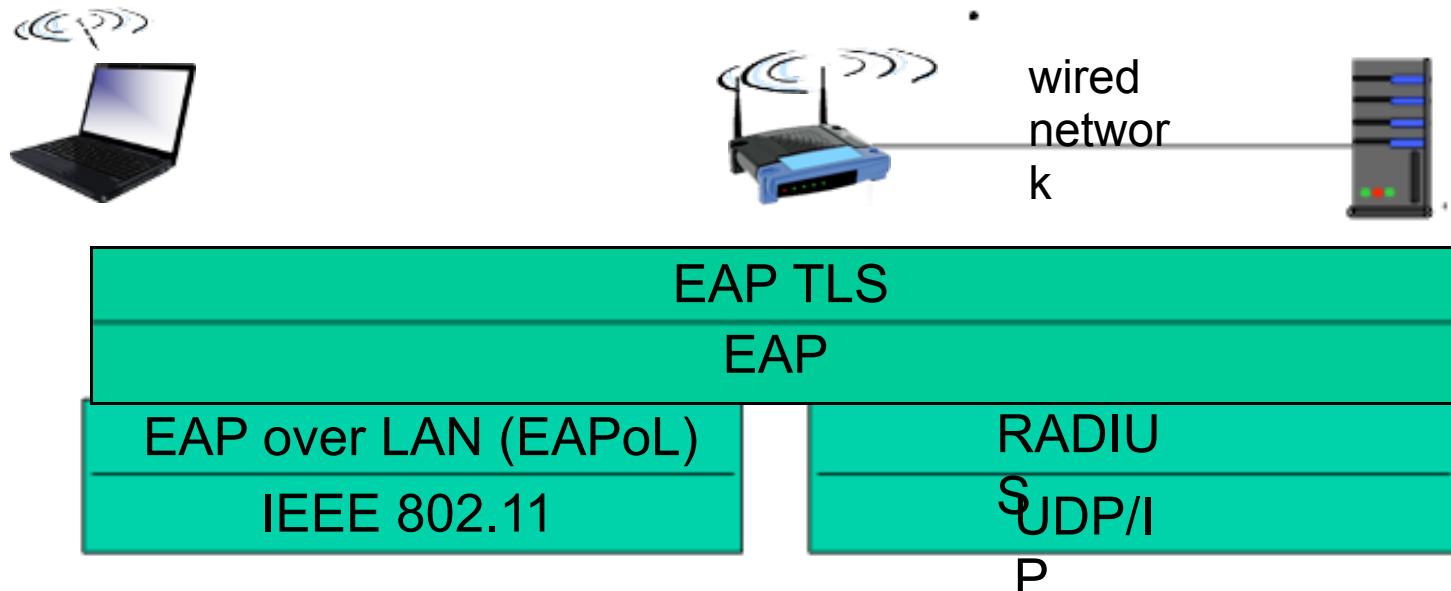

- numerous (stronger) forms of encryption possible
- provides key distribution
- uses authentication server separate from access point

802.11i: four phases of operation

EAP: extensible authentication protocol

- EAP: end-end client (mobile) to authentication server protocol
- EAP sent over separate “links”
 - mobile-to-AP (EAP over LAN)
 - AP to authentication server (RADIUS over UDP)

Chapter 8 roadmap

8.1 What is network security?

8.2 Principles of cryptography

8.3 Message integrity

8.4 Securing e-mail

8.5 Securing TCP connections: SSL

8.6 Network layer security: IPsec

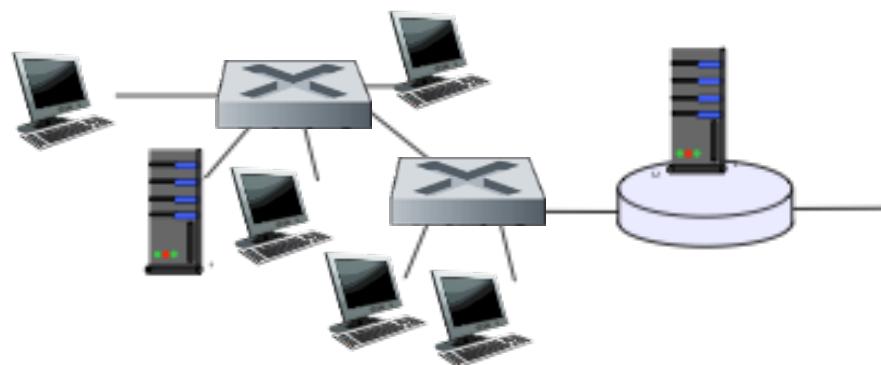

8.7 Securing wireless LANs

8.8 *Operational security: firewalls and IDS*

Firewalls

firewal

l isolates organization's internal net from larger Internet,
allowing some packets to pass, blocking others

administered
network

*trusted “good
guys”*

firewall

public
Internet

*untrusted “bad
guys”*

Firewalls: why

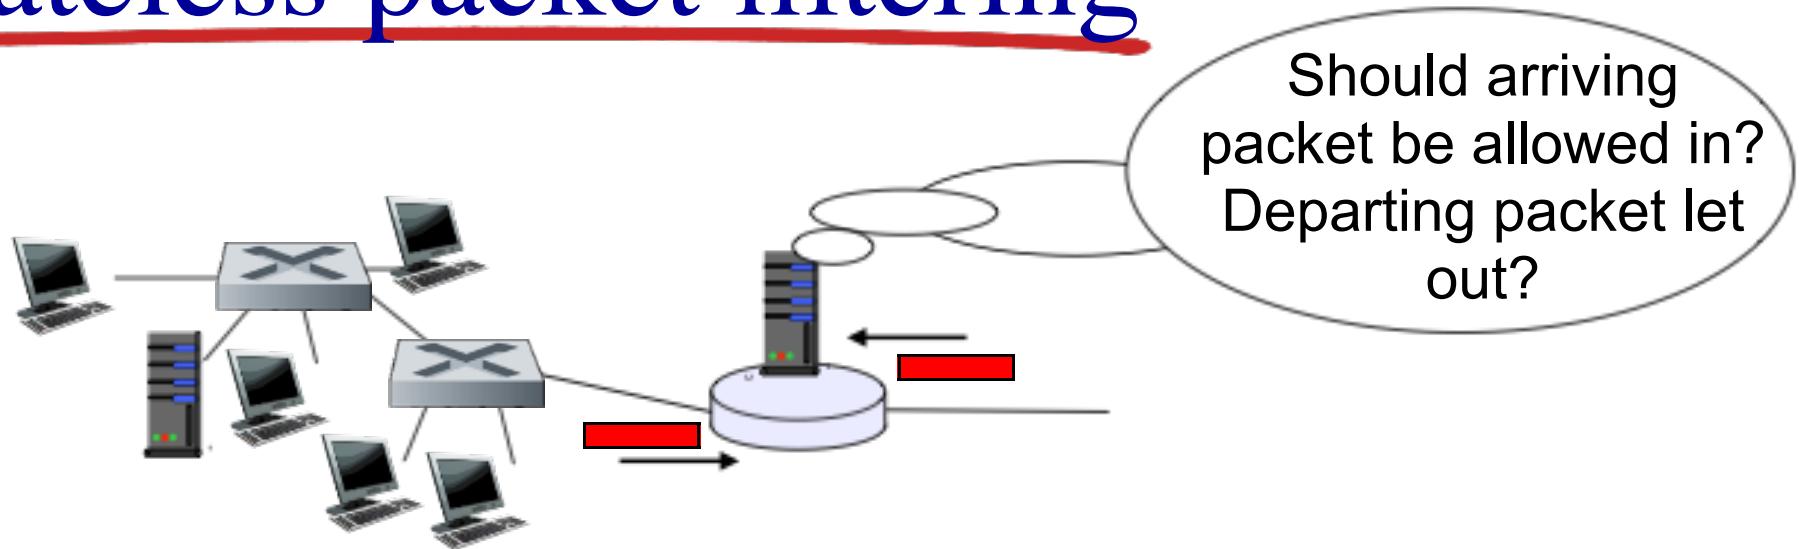

prevent denial of service attacks:

- SYN flooding: attacker establishes many bogus TCP connections, no resources left for “real” connections
- prevent illegal modification/access of internal data
- e.g., attacker replaces CIA’s homepage with something else
- allow only authorized access to inside network
- set of authenticated users/hosts

three types of firewalls:

- stateless packet filters
- stateful packet filters
- application gateways

Stateless packet filtering

- internal network connected to Internet via *router firewall*
- router *filters packet-by-packet*, decision to forward/drop packet based on:
 - source IP address, destination IP address
 - TCP/UDP source and destination port numbers
 - ICMP message type
 - TCP SYN and ACK bits

Stateless packet filtering: example

- *example 1:* block incoming and outgoing datagrams with IP protocol field = 17 and with either source or dest port = 23
 - *result:* all incoming, outgoing UDP flows and telnet connections are blocked
- *example 2:* block inbound TCP segments with ACK=0.
 - *result:* prevents external clients from making TCP connections with internal clients, but allows internal clients to connect to outside.

Stateless packet filtering: more examples

<i>Policy</i>	<i>Firewall Setting</i>
No outside Web access.	Drop all outgoing packets to any IP address, port 80
No incoming TCP connections, except those for institution's public Web server only.	Drop all incoming TCP SYN packets to any IP except 130.207.244.203, port 80
Prevent Web-radios from eating up the available bandwidth.	Drop all incoming UDP packets - except DNS and router broadcasts.
Prevent your network from being used for a smurf DoS attack.	Drop all ICMP packets going to a "broadcast" address (e.g. 130.207.255.255).
Prevent your network from being tracerouted	Drop all outgoing ICMP TTL expired traffic

Access Control Lists

ACL: table of rules, applied top to bottom to incoming packets:
(action, condition) pairs: looks like OpenFlow forwarding (Ch. 4)!

action	source address	dest address	protocol	source port	dest port	flag bit
allow	222.22/16	outside of 222.22/16	TCP	> 1023	80	any
allow	outside of 222.22/16	222.22/16	TCP	80	> 1023	ACK
allow	222.22/16	outside of 222.22/16	UDP	> 1023	53	---
allow	outside of 222.22/16	222.22/16	UDP	53	> 1023	----
deny	all	all	all	all	all	all

Stateful packet filtering

- *stateless packet filter*: heavy handed tool
 - admits packets that “make no sense,” e.g., dest port = 80, ACK bit set, even though no TCP connection established:

action	source address	dest address	protocol	source port	dest port	flag bit
allow	outside of 222.22/16	222.22/16	TCP	80	> 1023	ACK

- *stateful packet filter*: track status of every TCP connection
- track connection setup (SYN), teardown (FIN): determine whether incoming, outgoing packets “makes sense”
- timeout inactive connections at firewall: no longer admit packets

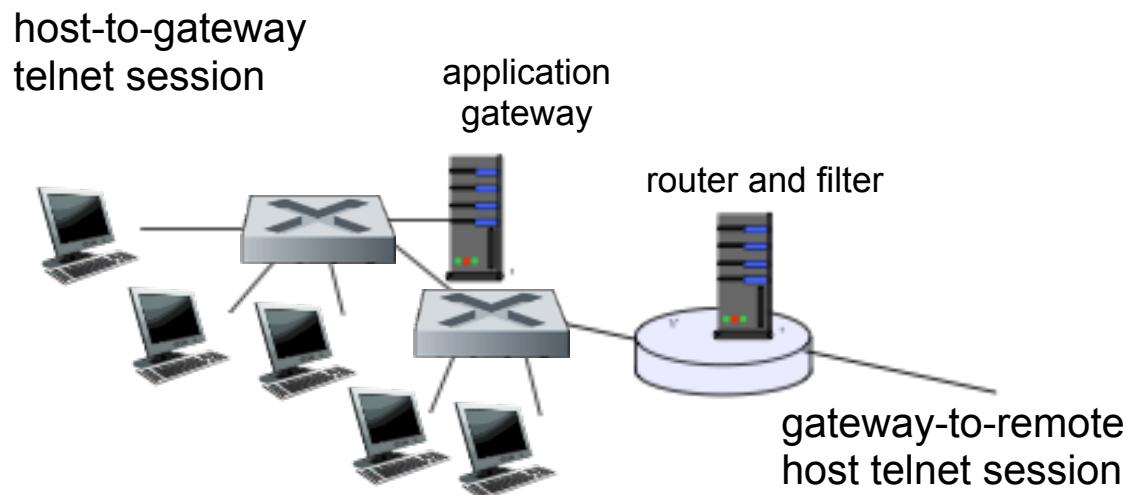

Stateful packet filtering

ACL augmented to indicate need to check connection state table before admitting packet

action	source address	dest address	proto	source port	dest port	flag bit	check conxion
allow	222.22/16	outside of 222.22/16	TCP	> 1023	80	any	
allow	outside of 222.22/16	222.22/16	TCP	80	> 1023	ACK	X
allow	222.22/16	outside of 222.22/16	UDP	> 1023	53	---	
allow	outside of 222.22/16	222.22/16	UDP	53	> 1023	----	X
deny	all	all	all	all	all	all	

Application gateways

- filter packets on application data as well as on IP/TCP/UDP fields.
- *example:* allow select internal users to telnet outside

1. require all telnet users to telnet through gateway.
2. for authorized users, gateway sets up telnet connection to dest host. Gateway relays data between 2 connections
3. router filter blocks all telnet connections not originating from gateway.

Limitations of firewalls, gateways

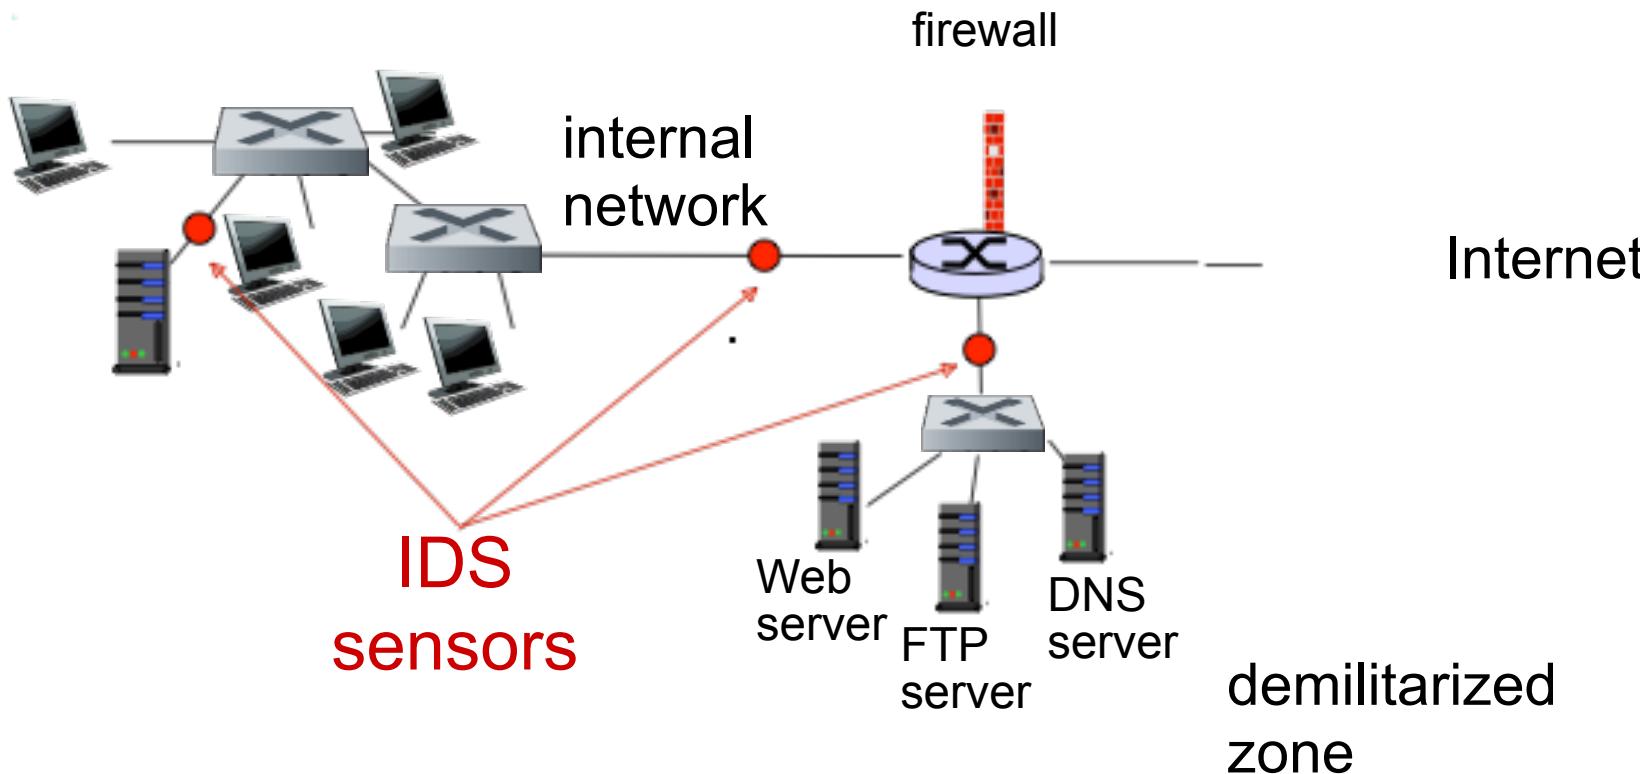

- *IP spoofing*: router can't know if data "really" comes from claimed source
- if multiple app's. need special treatment, each has own app. gateway
- client software must know how to contact gateway.
 - e.g., must set IP address of proxy in Web browser
- filters often use all or nothing policy for UDP
- *tradeoff*: degree of communication with outside world, level of security
- many highly protected sites still suffer from attacks

Intrusion detection systems

- packet filtering:
 - operates on TCP/IP headers only
 - no correlation check among sessions
- *IDS: intrusion detection system*
 - *deep packet inspection*: look at packet contents (e.g., check character strings in packet against database of known virus, attack strings)
 - examine correlation among multiple packets
 - port scanning
 - network mapping
 - DoS attack

Intrusion detection systems

multiple IDSs: different types of checking at different locations

Network Security (summary)

basic techniques.....

- cryptography (symmetric and public)
- message integrity
- end-point authentication

.... used in many different security scenarios

- secure email
- secure transport (SSL)
- IP sec
- 802.11

operational security: firewalls and IDS
